Contributors

The NYS Workers’ Compensation Board would like to thank the members of the New York Workers’ Compensation Board Medical Advisory Committee (MAC). The MAC served as the Board’s advisory body to adapt the American College of Occupational and Environmental Medicine (ACOEM) Practice Guidelines to a New York version of the Medical Treatment Guidelines (MTG). In this capacity, the MAC provided valuable input and made recommendations to help guide the final version of these Guidelines. With full consensus reached on many topics, and a careful review of any dissenting opinions on others, the Board established the final product.

Medical Advisory Committee

Joseph Canovas, Esq.
Special Counsel
New York State AFL-CIO

Kenneth B. Chapman, MD
Director Pain Medicine, SIUH Northwell Health Systems
Assistant Clinical Professor, NYU Langone Medical Center
Adjunct Assistant Professor, Hofstra Medical School

Nicholas D’Angelo, DPM
ABPS, Board Certified in Foot Surgery
NYSPMA, Board of Trustees
NYSPMA, Insurance Committee Chair

Lev Ginsburg, Esq.
Senior Director of Government Affairs
The Business Council of New York State

Emilio A. Goez, DPM, FACAS, FASPS
St. Barnabas Hospital Health System, Medical Co-Director, The Center for Wound Healing and Hyperbaric Medicine
Board Certified, Board of Foot and Ankle Surgery
Fellow, American Society of Podiatric Surgeons, the American College of Foot and Ankle Surgeons and the American Professional Wound Care Association

Robert Goldberg, DO
Attending Physician, Department of Rehabilitation, Beth Israel Hospital and Medical Center of NYC
Professor of Physical Medicine and Rehabilitation and Health Policy
Clinical Associate Professor of Rehabilitation Medicine, New York Medical College
Clinical Professor of Rehabilitation Medicine, Philadelphia College of Osteopathic Medicine
Member, Council on Medical Education of the American Medical Association

Brian M. Gordon, MD
Former Medical Director,
New York State Workers’ Compensation Board

Charles M. Lombardi, DPM
Director of Podiatry, Department of Orthopaedics & Rehabilitation, New York-Presbyterian/Queens
Clinical Assistant Professor of Podiatry in Surgery, Cornell University Medical College, New York Clinical Associate Professor of Surgery, External Faculty, New York College of Podiatric Medicine
Director of Podiatric Medical Education, New York-Presbyterian/Queens, New York.
Joseph Pachman, MD, PhD, MBA, MPH
Licensed Psychologist and Physician
Board Certified in Occupational Medicine
Fellow in ACOEM
Vice President and National Medical Director, Liberty Mutual

Elaine Sobol-Berger, MD, JD
Former Medical Director and Senior Policy Advisor,
New York State Workers' Compensation Board

James A. Tacci, MD, JD, MPH
Medical Director and Executive Medical Policy Director,
New York State Workers’ Compensation Board
(At the time of drafting: Attending Physician, Associate Professor, and Medical Director, University of Rochester Medical Center)

Edward C. Tanner, MD
Chair, Department of Orthopaedics at Rochester General Hospital
Past President, New York State Society of Orthopaedic Surgeons (NYSSOS)
Member, American Academy of Orthopaedic Surgeons (AAOS)
Member, American Association of Hip and Knee Surgeons (AAHKS)

Contributors to ACOEM Ankle and Foot Disorders Guideline

Editor-in-Chief:
Kurt T. Hegmann, MD, MPH, FACOEM, FACP

Assistant Editor:
Matthew A. Hughes, MD, MPH

Evidence-based Practice Ankle and Foot Panel Chair:
Nelson S. Haas, MD, MPH, FACOEM

Evidence-based Practice Ankle and Foot Panel Members:
Patrick J. Beecher, MD, MPH, MBA, FACOEM
Mark Easley, MD
Hannah Edwards, MD, MPH
Harold Hoffman, MD, FRCPC
Steven Mandel, MD, FACOEM
RobRoy L. Martin, PhD, PT, CSCS
Pete Thomas, DPM, QME

The Evidence-based Practice Ankle/Foot Panel represents expertise in occupational medicine, neurology, podiatric surgery, foot and ankle surgery, physical therapy, and rehabilitation science.

Guidelines Methodology Consultant:
Kurt T. Hegmann, MD, MPH, FACOEM, FACP

Research Conducted By:
Kurt T. Hegmann, MD, MPH, FACOEM, FACP
Matthew A. Hughes, MD, MPH

A. GENERAL GUIDELINE PRINCIPLES
The principles summarized in this section are key to the intended application of the New York State Medical Treatment Guidelines (MTG) and are applicable to all Workers’ Compensation Medical Treatment Guidelines.

A.1 Medical Care
Medical care and treatment required as a result of a work-related injury should be focused on restoring functional ability required to meet the patient’s daily and work activities with a focus on a return to work, while striving to restore the patient’s health to its pre-injury status in so far as is feasible.

A.2 Rendering Of Medical Services
Any medical provider rendering services to a workers’ compensation patient must utilize the Treatment Guidelines as provided for with respect to all work-related injuries and/or illnesses.

A.3 Positive Patient Response
Positive results are defined primarily as functional gains which can be objectively measured. Objective functional gains include, but are not limited to, positional tolerances, range of motion, strength, endurance, activities of daily living (ADL), cognition, psychological behavior, and efficiency/velocity measures which can be quantified. Subjective reports of pain and function may be considered and given relative weight when the pain has anatomic and physiologic correlation in proportion to the injury.

A.4 Re-Evaluate Treatment
If a given treatment or modality is not producing positive results within a well-defined timeframe, the provider should either modify or discontinue the treatment regime. The provider should evaluate the efficacy of the treatment or modality 2 to 3 weeks after the initial visit and 3 to 4 weeks thereafter. These timeframes may be slightly longer in the context of conditions that are inherently mental health issues, and shorter for other non-musculoskeletal medical conditions (e.g. pulmonary, dermatologic etc.). Recognition that treatment failure is at times attributable to an incorrect diagnosis a failure to respond should prompt the clinician to reconsider the diagnosis in the event of an unexpected poor response to an otherwise rational intervention.

A.5 Education
Education of the patient and family, as well as the employer, insurer, policy makers and the community should be a primary emphasis in the treatment of work-related injury or illness. Practitioners should develop and implement effective educational strategies and skills. An education-based paradigm should always start with communication providing reassuring information to the patient. No treatment plan is complete without addressing issues of individual and/or group patient education as a means of facilitating self-management of symptoms and prevention of future injury.
Time Frames

A.6 Acuity
Acute, Subacute and Chronic are generally defined as timeframes for disease stages:
- **Acute** – Less than one month
- **Subacute** – One to three months, and
- **Chronic** – greater than three months.

A.7 Initial Evaluation
Initial evaluation refers to the acute timeframe following an injury and is not used to define when a given physician first evaluates an injured worker (initial encounter) in an office or clinical setting.

A.8 Diagnostic Time Frames
Diagnostic time frames for conducting diagnostic testing commence on the date of injury. Clinical judgment may substantiate the need to accelerate or decelerate the time frames discussed in this document.

A.9 Treatment Time Frames
Treatment time frames for specific interventions commence once treatments have been initiated, not on the date of injury. It is recognized that treatment duration may be impacted by disease process and severity, patient compliance, as well as availability of services. Clinical judgment may substantiate the need to accelerate or decelerate the time frames discussed in this document.

A.10 Delayed Recovery
For those patients who fail to make expected progress 6-12 weeks after an injury and whose subjective symptoms do not correlate with objective signs and tests, reexamination in order to confirm the accuracy of the diagnosis and re-evaluation of the treatment program should be performed. When addressing a clinical issue that is not inherently a mental health issue, assessment for potential barriers to recovery (yellow flags/psychological issues) should be ongoing throughout the care of the patient. At 6-12 weeks, alternate treatment programs, including formal psychological or psychosocial evaluation should be considered. Clinicians must be vigilant for any pre-existing mental health issues or subsequent, consequential mental health issues that may be impacting recovery. For issues that are clearly and inherently mental health issues from the outset (i.e. when it is evident that there is an underlying, work-related, mental health disorder as part of the claim at issue), referral to a mental health provider can and should occur much sooner. Referrals to mental health providers for the evaluation and management of delayed recovery do not indicate or require the establishment of a psychiatric or psychological condition. The evaluation and management of delayed recovery does not require the establishment of a psychiatric or psychological claim.
Treatment Approaches

A.11 Active Interventions
Active interventions emphasizing patient responsibility, such as therapeutic exercise and/or functional treatment, are generally emphasized over passive modalities, especially as treatment progresses. Generally, passive and palliative interventions are viewed as a means to facilitate progress in an active rehabilitation program with concomitant attainment of objective functional gains.

A.12 Active Therapeutic Exercise Program
Active therapeutic exercise program goals should incorporate patient strength, endurance, flexibility, range of motion, sensory integration, coordination, cognition and behavior (when at issue) and education as clinically indicated. This includes functional application in vocational or community settings.

A.13 Diagnostic Imaging And Testing Procedures
Clinical information obtained by history taking and physical examination should be the basis for selection of imaging procedures and interpretation of results. All diagnostic procedures have characteristic specificities and sensitivities for various diagnoses. Usually, selection of one procedure over others depends upon various factors, which may include: relative diagnostic value; risk/benefit profile of the procedure; availability of technology; a patient’s tolerance; and/or the treating practitioner’s familiarity with the procedure.

When a diagnostic procedure, in conjunction with clinical information, provides sufficient information to establish an accurate diagnosis, a second diagnostic procedure is not required. However, a subsequent diagnostic procedure including a repeat of the original (same) procedure can be performed, when the specialty physician (e.g. physiatrist, sports medicine physician or other appropriate specialist) radiologist or surgeon documents that the initial study was of inadequate quality to make a diagnosis. Therefore, in such circumstances, a repeat or complementary diagnostic procedure is permissible under the MTG.

It is recognized that repeat imaging studies and other tests may be warranted by the clinical course and/or to follow the progress of treatment in some cases. It may be of value to repeat diagnostic procedures (e.g., imaging studies) during the course of care to reassess or stage the pathology when there is progression of symptoms or findings, prior to surgical interventions and/or therapeutic injections when clinically indicated, and post-operatively to follow the healing process. Regarding serial imaging, (including x-rays, but particularly CT scans), it must be recognized that repeat procedures result in an increase in cumulative radiation dose and associated risks.

A given diagnostic imaging procedure may provide the same or distinctive information as obtained by other procedures. Therefore, prudent choice of procedures(s) for a single diagnostic procedure, a complementary procedure in combination with other procedures(s), or a proper sequential order in multiple procedures will ensure maximum diagnostic accuracy, minimize the likelihood of adverse effect on patients, and promote efficiency by avoiding duplication or redundancy.
A.14 Surgical Interventions
Consideration of surgery should be within the context of expected functional outcome. The concept of "cure" with respect to surgical treatment by itself is generally a misnomer. All operative interventions must be based upon positive correlation of clinical findings, clinical course and imaging and other diagnostic tests. A comprehensive assimilation of these factors must lead to a specific diagnosis with positive identification of pathologic condition(s). For surgery to be performed to treat pain, there must be clear correlation between the pain symptoms and objective evidence of its cause. In all cases, shared decision making with the patient is advised. The patient should be given the opportunity to understand the pros and cons of surgery, potential for rehabilitation as an alternative where applicable, evidence-based outcomes, and specific surgical experience.

A.15 Pre-Authorization
All diagnostic imaging, testing procedures, non-surgical and surgical therapeutic procedures, and other therapeutics within the criteria of the Medical Treatment Guidelines and based on a correct application of the Medical Treatment Guidelines are considered authorized, with the exception of the procedures listed in section 324.3(1)(a) of Title 12 NYCRR. These are not included on the list of pre-authorized procedures. Providers who want to perform one of these procedures must request pre-authorization from the carrier before performing the procedure.

Second or subsequent procedures (the repeat performance of a surgical procedure due to failure of, or incomplete success from the same surgical procedure performed earlier, if the Medical Treatment Guidelines do not specifically address multiple procedures) also require pre-authorization.

A.16 Psychological/Psychiatric Evaluations
In select patients, mental health evaluations are essential to make, secure or confirm a diagnosis. Of course, the extent and duration of evaluations and/or interventions by mental health professionals may vary, particularly based on whether: the underlying clinical issue in the claim is inherently a mental health issue; or there is a mental health issue that is secondary or consequential to the medical injury or illness that is at issue in the claim in question; or there is a pre-existing, unrelated mental health issue that has been made worse by, or is impeding the recovery from (or both) the medical injury or illness that is at issue in the claim in question.

Tests of psychological function or psychometric testing, when indicated, can be a valuable component of the psychological evaluation in identifying associated psychological, personality and psychosocial issues. Although these instruments may suggest a diagnosis, neither screening nor psychometric tests are capable of making a diagnosis. The diagnosis should only be made after careful analysis of all available data, including from a thorough history and clinical interview.

A professional fluent in the primary language of the patient is strongly preferred. When such a provider is not available, services of a professional language interpreter must be provided.

Frequency: When assessing for a pre-existing, unrelated mental health issue that has been made worse by, or is impeding the recovery from (or both) a work-related, medical injury or illness, then a one-time visit for initial psychiatric/psychological encounter should
be sufficient, as care would normally be continued by the prior treating provider. If psychometric testing is indicated by findings in the initial encounter, time for such testing should not exceed an additional three hours of professional time. For conditions in which a mental health issue is a central part of the initial claim, or in which there is a mental health issue that is secondary or consequential to the work-related, medical injury or illness, that is part of the claim in question, then more extensive diagnostic and therapeutic interventions may be clinically indicated, and are discussed in detail in the Medical Treatment Guidelines for such mental health conditions.

A.17 Personality/Psychological/Psychosocial Intervention

Following psychosocial evaluation, when intervention is recommended, such intervention should be implemented as soon as possible. This can be used alone or in conjunction with other treatment modalities. For all psychological/psychiatric interventions, there must be an assessment and treatment plan with measurable behavioral goals, time frames and specific interventions planned.

- Time to produce effect: two to eight weeks.
- Optimum duration: six weeks to three months.
- Maximum duration: three to six months.
- Counseling is not intended to delay but rather to enhance functional recovery.

For PTSD Psychological Intervention:

- Optimum duration three to six months.
- Maximum duration: nine to twelve months.

For select patients, longer supervision and treatment may be required, and if further treatment is indicated, documentation of the nature of the psychological factors, as well as projecting a realistic functional prognosis, should be provided by the authorized treating practitioner every four weeks during the first six months of treatment. For treatment expected to last six to twelve months, such documentation should be provided every four to eight weeks. For long-term treatment beyond twelve months, such documentation should be provided every eight to twelve weeks. All parties should strive for ongoing and continuous communications, in order to facilitate seamless, continuous and uninterrupted treatment.

A.18 Functional Capacity Evaluation (FCE)

Functional capacity evaluation is a comprehensive or more restricted evaluation of the various aspects of function as they relate to the patient’s ability to return to work. Areas such as endurance, lifting (dynamic and static), postural tolerance, specific range-of-motion, coordination and strength, worker habits, employability, as well as psychosocial, cognitive, and sensory perceptual aspects of competitive employment may be evaluated. Components of this evaluation may include: (a) musculoskeletal screen; (b) cardiovascular profile/aerobic capacity; (c) coordination; (d) lift/carrying analysis; (e) job-specific activity tolerance; (f) maximum voluntary effort; (g) pain assessment/psychological screening; (h) non-material and material handling activities; (i) cognitive and behavioral; (j) visual; and (k) sensory perceptual factors.

In most cases, the question of whether a patient can return to work can be answered without an FCE.
An FCE may be considered at time of MMI, following reasonable prior attempts to return to full duty throughout course of treatment, when the treating physician is unable to make a clear determination on work status on case closure. An FCE is not indicated early during a treatment regime for any reason including one to support a therapeutic plan.

When an FCE is being used to determine return to a specific job site, the treating physician is responsible for understanding and considering the job duties. FCEs cannot be used in isolation to determine work restrictions. The authorized treating physician must interpret the FCE in light of the individual patient's presentation and medical and personal perceptions. FCEs should not be used as the sole criteria to diagnose malingering.

A.19 Return To Work
For purposes of these guidelines, return to work is defined as any work or duty that the patient is able to perform safely. It may not be the patient’s regular work. Ascertaining a return to work status is part of medical care, and should be included in the treatment and rehabilitation plan. It is normally addressed at every outpatient visit. A description of the patient’s status and task limitations is part of any treatment plan and should provide the basis for restriction of work activities when warranted. Early return to work should be a prime goal in treating occupational injuries. The emphasis within these guidelines is to move patients along a continuum of care and return to work, since the prognosis of returning an injured worker to work drops progressively the longer the worker has been out of work.

A.20 Job Site Evaluation
The treating physician may communicate with the employer or employer’s designee, either in person, by video conference, or by telephone, to obtain information regarding the individual or specific demands of the patient’s pre-injury job. This may include a description of the exertional demands of the job, the need for repetitive activities, load lifting, static or awkward postures, environmental exposures, psychological stressors and other factors that would pose a barrier to re-entry, risk of re-injury or disrupt convalescence. When returning to work at the patient’s previous job tasks or setting is not feasible, given the clinically determined restrictions on the patient’s activities, inquiry should be made about modified duty work settings that align with, the patient’s condition in view of proposed work activities/demands in modified duty jobs. It should be noted, that under certain circumstances, more than one job site evaluation may be indicated.

Ideally, the physician would gain the most information from an on-site inspection of the job settings and activities; but it is recognized that this may not be feasible in most cases. If job videos/CDs/DVDs are available from the employer, these can contribute valuable information, as can video conferences, conducted from the worksite and ideally workstation or work area.

Frequency: one or two contacts.
- 1st contact: Patient is in a functional state where the patient can perform some work.
- 2nd contact: Patient has advanced to state where the patient is capable of enhanced functional demands in a work environment.

The physician shall document the conversation.
Other

A.21 Guideline Recommendations And Medical Evidence
The Workers’ Compensation Board and its Medical Advisory Committee have not independently evaluated or vetted the scientific medical literature used in support of the guidelines, but have relied on the methodology used by the developers of various guidelines utilized and referenced in these Guidelines.

A.22 Experimental/Investigational Treatment
Medical treatment that is experimental/investigational and not approved for any purpose, application or indication by the FDA is not permitted under these Guidelines.

A.23 Injured Workers As Patients
In these Guidelines, injured workers are referred to as patients recognizing that in certain circumstances there is no doctor-patient relationship.

A.24 Scope Of Practice
These Guidelines do not address scope of practice or change the scope of practice.
B. Introduction

This guideline addresses common and potentially work-related ankle and foot injuries. It encompasses assessment; including identification of “red flags” or indicators of potentially-serious injury or disease; diagnosis; diagnostic studies for identification of clinical pathology and management. Red flags include fracture, dislocation, malignancy, metabolic disorders, infection, and other conditions.

B.1 History Taking and Physical Examination

B.1.a History Taking and Physical Examination

History taking and physical examination establish the foundation/basis for and dictate subsequent stages of diagnostic and therapeutic procedures. When findings of clinical evaluations and those of other diagnostic procedures are not consistent with each other, the objective clinical findings should have preference. The medical records should reasonably document the following:

B.1.b History of Present Injury

- Mechanism of injury: This includes details of symptom onset and progression, and symptoms that may arise from postural or functional accommodation to the Ankle-Foot injury;
- Relationship to work: This includes a statement of the probability that the illness or injury is work-related;
- Prior occupational and non-occupational injuries: To the same area including specific prior treatment;
- Ability to perform job duties and activities of daily living; and
- Exacerbating and alleviating factors for symptoms; not limited to the Ankle-Foot.

B.1.c Past History

- Past medical history includes, but is not limited to, neoplasm, gout, arthritis, and diabetes;
- Review of systems includes, but is not limited to, symptoms of rheumatologic, neurologic, endocrine, neoplastic, and other systemic diseases;
- Smoking history;
- Vocational and recreational pursuits;
- Prior imaging studies; and
- Past surgical history.

B.1.d Physical Examination

Examination of a joint should include the joint above and below the affected area, including the opposite side for comparison. Physical examination should include
accepted tests and exam techniques applicable to the joint or area being examined, including:

- Visual inspection - Examine both feet and look for and note asymmetries and for deformities suggestive of degeneration, malformation, fracture, or dislocations. Observe for signs of serious injuries, e.g., degloving injuries, lacerations, puncture wounds, open wounds and crush injuries;
- Palpation;
- Range of motion/quality of motion (active and passive); The range of motion (ROM) of the foot and ankle should be determined both actively and passively. Compare mobility of the affected and unaffected side;
- Strength (weakness / atrophy);
- Joint integrity / stability - Stress the ligaments to assess the stability and compare to contralateral unaffected side;
- Examination for deformity/displacement; and
- Assess neurologic (motor, sensory and reflexes) and vascular status (integrity of distal circulation, peripheral pulses, skin temperature) of the foot and ankle, as clinically indicated. Observe for signs of serious injuries, e.g., degloving injuries, lacerations, puncture wounds open wounds and crush injuries.

B.2 Assessing Red Flags

Certain findings, “red flags” raise suspicion of potentially serious medical conditions. Assessment (history and physical examination) should include evaluation for red flags. In the foot and ankle these findings or indicators may include: fracture, dislocations, infection or inflammation, tumor, tendon rupture and neurological or vascular compromise including compartment syndrome. Further evaluation/consultation or urgent/emergency intervention may be indicated, and the New York Ankle and Foot Injury Medical Treatment Guidelines incorporate changes in clinical management triggered by the presence of “red flags”.

</table>
progressive flatfoot deformity (with or without pain)
May have sustained laceration, open wounds, crush injuries, or direct trauma
May have degloving injury

asymmetrical flatfoot, difficulty with ipsilateral heel raise
May have overlying signs of trauma including laceration, open wounds, puncture wounds, or crush injuries

B.3 Diagnostic Criteria and Differential Diagnosis

For most cases presenting with true foot and ankle disorders, diagnostic studies are usually not needed until after a period of conservative care and observation. Most ankle and foot problems improve quickly once any red flags are ruled out. Routine testing, i.e., laboratory tests, plain-film radiographs of the foot or ankle, or special imaging studies are not recommended during the first month of activity limitation except when a red flag that is noted on history or examination raises suspicion of a dangerous foot or ankle condition or of referred pain.

B.3.a Diagnostic Testing and Procedures

One diagnostic imaging procedure may provide the same or distinctive information as obtained by other procedures. Therefore, prudent choice of procedure(s) for a single diagnostic procedure, a complementary procedure in combination with other procedures(s), or a proper sequential order in multiple procedures will ensure maximum diagnostic accuracy, minimize adverse effect to patients and promote cost effectiveness by avoiding duplication or redundancy.

All diagnostic imaging procedures have a significant percentage of specificity and sensitivity for various diagnoses. None is specifically characteristic of a certain diagnosis. Clinical information obtained by history taking and physical examination should be the basis for selection and interpretation of imaging procedure results.

When a diagnostic procedure, in conjunction with clinical information, provides sufficient information to establish an accurate diagnosis, the second diagnostic procedure will be redundant if it is performed only for diagnostic purposes. At the same time, a subsequent diagnostic procedure (that may be a repeat of the same procedure, when the rehabilitation physician, radiologist or surgeon documents that the study was of inadequate quality to make a diagnosis) can be a complementary diagnostic procedure if the first or preceding procedures, in conjunction with clinical information, cannot provide an accurate diagnosis. Usually, preference of a procedure over others depends upon availability, a patient’s tolerance, and/or the treating practitioner’s familiarity with the procedure.

It is recognized that repeat imaging studies and other tests may be warranted by the clinical course and to follow the progress of treatment in some cases. It may be of value to repeat diagnostic procedures (e.g. imaging studies) during the course of care to reassess or stage the pathology when there is progression of symptoms or findings, prior to surgical interventions and therapeutic injections when warranted, and post-operatively to follow the healing process. Regarding CT examinations, it must be recognized that repeat procedures result in an increase in cumulative radiation dose and associated risks.

When indicated, the following can be utilized for further evaluation of foot and ankle injuries, based upon the mechanism of injury, symptoms, and patient history.

C. Conditions: This guideline addresses the following Foot and Ankle Disorders

C.1 Achilles Tendinopathy
C.2 Achillies Tendon Rupture
C.3 Ankle Tendinopathies
C.4 Tenosynovitis
C.5 Plantar Heel Pain (Plantar Fasciitis)
C.6 Foot Ulceration
C.7 Wound Care, Subungual Hematoma, Contusions
C.8 Charcot Joint (Neurogenic Arthropathy)
C.9 Paronychia
C.10 Foot Drop
C.11 Tarsal Tunnel Syndrome (TTS)
C.12 Ankle Sprain
C.13 Mid-Tarsus Pain and Sprains
C.14 Foot Neuroma (Morton’s Neuroma)
C.15 Bunions / Halus Valgus
C.16 Hammer Toe
C.17 Ankle and Foot Fractures
C.18 Hindfoot Fractures / calcaneus, Talus)
C.19 Forefoot and Midfoot Fractures (Tarsal, Metatarsal, Phalangeal)
C.1 Achilles Tendinopathy

Achilles tendon disorders, including Achilles tendinitis, tendinosis, or tendinopathy, are painful conditions affecting the Achilles tendon, which is the largest and strongest tendon in the body, connecting the soleus, and gastrocnemius muscles in the leg to the heel at the calcaneus bone. The Achilles tendon plantar flexes the ankle and facilitates walking. Achilles tendon disorders can make walking difficult.

For each of the Achilles tendon disorders causing pain, the initial management is non-operative. It is believed that early intervention is critical, as management becomes more complicated and less predictable when the conditions become chronic.

C.1.a Diagnostic Studies

Although diagnosing of non-rupture Achilles disorders is largely based on a careful history and examination, diagnostic imaging may be required to verify a clinical suspicion or to exclude other musculoskeletal disorders.

C.1.a.i X-ray for Diagnosis of Achilles Tendon Disorders, Retrocalcaneal Bursitis, or Blunt Trauma or Suspected Fracture

Recommended – for diagnosing insertional Achilles tendon disorders or retrocalcaneal bursitis or evaluating blunt trauma or suspected fracture.

Rationale for Recommendation: Radiography is poor at diagnosing soft-tissue disorders, and in the absence of trauma or suspected fracture, is not indicated as a first-line diagnostic tool for mid-portion tendon disorders. X-ray may reveal calcaneal spur, prominent posterior calcaneal tuberosity, or ossification of the Achilles tendon. For other Achilles disorders, ultrasound or MRI are more effective. Therefore, plain radiographic film studies are recommended only for insertional Achilles tendinopathy or traumatic injury.

C.1.a.ii Ultrasound for Diagnosis of Achilles Tendinopathy

Recommended - for diagnosing Achilles tendinopathy and may be particularly useful for differentiation of paratenonitis and tendinosis and for identifying fluid in the retrocalcaneal bursa.

Rationale for Recommendation: Ultrasound is frequently used to diagnose midportion tendinopathy.

C.1.a.iii Magnetic Resonance Imaging (MRI) for Diagnosis of Achilles Tendinopathy

Recommended - for evaluating Achilles tendinopathies including paratendonitis, tendinosis, and retrocalcaneal bursitis.

Rationale for Recommendation: MRI can demonstrate thickened paratenon with adhesions and offers extensive information on the internal structure of the tendon and surrounding tissues. MRI may be
helpful in differentiating inflammatory from degenerative changes in soft tissue.

C.1.a.iv CT for Diagnosis of Achilles Tendinopathy

Not Recommended - for diagnosing Achilles tendinopathy.

Rationale for Recommendation: CT is not helpful in differentiating inflammatory from degenerative changes in soft tissue. As CT has limitations when compared to MRI, it is not recommended.

C.1.b Medications

For most patients, ibuprofen, naproxen, or other older generation nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence suggests acetaminophen is modestly less effective. There is evidence that NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.

C.1.b.i Non-steroidal Anti-inflammatory Drugs (NSAIDs) for Treatment of Acute, Subacute, Chronic, or Post-operative Achilles Tendinopathy Pain

Recommended - for treatment of acute, subacute, chronic, or post-operative Achilles tendinopathy pain.

Indications: For acute, subacute, chronic, or post-operative Achilles tendinopathy, NSAIDs are recommended for treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

Frequency/Duration: As needed use may be reasonable for many patients.

Indications for Discontinuation: Resolution of foot/ankle pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.

C.1.b.ii NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding

Recommended – concomitant use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine Type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

Indications: For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.

Frequency/Dose/Duration: Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per
manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding.

*Indications for Discontinuation:* Intolerance, development of adverse effects, or discontinuation of NSAID.

**C.1.b.iii** NSAIDs for Patients at Risk for Cardiovascular Adverse Effects

Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.

**Recommended** - Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse effects.

**Recommended** - If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to minimize the potential for the NSAID to counteract the beneficial effects of aspirin, the NSAID should be taken at least 30 minutes after or eight hours before the daily aspirin.

*Evidence for the Use of NSAIDs and Acetaminophen*

**C.1.b.iv** Acetaminophen for Treatment of Acute, Subacute, or Chronic Achilles Tendinopathy Pain

**Recommended** - for treatment of acute, subacute, or chronic Achilles Tendinopathy Pain, particularly in patients with contraindications for NSAIDs.

*Indications:* All patients with foot/ankle pain, including acute, subacute, chronic, and postoperative.

*Dose/Frequency:* Per manufacturer’s recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

*Indications for Discontinuation:* Resolution of pain, adverse effects or intolerance.

**C.1.b.v** Systemic Corticosteroids (oral or intermuscular preparations) for Treatment of Acute, Subacute, Chronic, or Postoperative Achilles Tendinopathy

**Not Recommended** - for the treatment of acute, subacute, chronic, or postoperative Achilles tendinopathy.

**C.1.b.vi** Opioids for Treatment of Acute, Subacute, or Chronic Achilles Tendinopathy Pain

**Not Recommended** - for treatment of acute, subacute, or chronic Achilles tendinopathy pain.
C.1.b.vii Opioids for Treatment of Pain for Postoperative Achilles Tendinopathy

**Recommended** - for short-term (not to exceed seven days) use to treat pain after Achilles tendon surgery or for patients who have encountered surgical complications.

*Indications*: Postoperative pain management.

*Frequency/Dose/Duration*: Frequency and dose per manufacturer's recommendations; total treatment length usually ranges from a few days to a maximum of seven days.

*Indications for Discontinuation*: Sufficient pain management with other methods such as NSAIDs, resolution of pain, intolerance, adverse effects, lack of benefits, or failure to progress over a couple weeks.

*Rationale for Recommendations*: The vast majority of patients with Achilles tendinopathy do not have pain sufficient to require opioids. Patients with such degrees of pain should generally have investigations performed for alternative diagnoses. Opioids are not recommended for routine use.

C.1.b.viii Vitamin Therapy for Treatment of Achilles Tendinopathy

**Not Recommended** - as a therapeutic intervention or for prevention of Achilles tendinopathy.

C.1.b.ix High-dose Vitamin Therapy for Treatment of Achilles Tendinopathy

**Not Recommended** - for prevention of Achilles tendinopathy.

C.1.b.x Topical NSAIDs for Acute, Subacute, or Chronic Achilles Tendinopathy

**Recommended** - for treatment of acute, subacute, or chronic Achilles tendinosis.

*Indications*: Mild, moderate, or severe Achilles tendinopathy.

*Frequency/Duration*: Frequency per manufacturer's recommendation.

*Indications for Discontinuation*: Resolution, intolerance, adverse effects, or lack of benefits.

C.1.b.xi Topical NSAIDs for Postoperative Achilles Tendinopathy

**Not Recommended** - for treatment of postoperative Achilles tendinosis.

Evidence for the Use of Topical NSAIDs

C.1.b.xii Lidocaine Patches for Acute, Subacute, Chronic, or Postoperative Achilles Tendinopathy
Not Recommended - for the treatment of acute, subacute, chronic, or postoperative Achilles tendinopathy.

C.1.c Treatments

C.1.c.i Cryotherapy / Heat

C.1.c.i.a Cryotherapy for Acute, Subacute, Chronic, or Postoperative Achilles Tendinopathy

Recommended - for acute, subacute, chronic, or postoperative Achilles tendinopathy.

Indications: All patients with Achilles tendinopathy.

Frequency/Duration: Approximately three to five self-applications per day as needed.

Indications for Discontinuation: Resolution, adverse effects, noncompliance.

C.1.c.i.b Heat Therapy for Acute, Subacute, Chronic, or Postoperative Achilles Tendinopathy

Recommended - for acute, subacute, chronic, or postoperative Achilles tendinopathy.

Indications: All patients with Achilles tendinopathy.

Frequency/Duration: Approximately three to five self-applications per day as needed.

Indications for Discontinuation: Resolution, adverse effects, noncompliance.

Evidence for the Use of Cryotherapy and Heat for Achilles Tendinopathy

C.1.c.ii Mobilization / Immobilization

C.1.c.ii.a Night Splints for Acute, Subacute, or Chronic Achilles Tendinopathy

Not Recommended - for treatment of acute, subacute, or chronic Achilles tendinopathy.

C.1.c.ii.b Night Splints and Walking Boots for Postoperative Achilles Tendinopathy

Recommended - for postoperative Achilles tendinopathy patients.
C.1.c.iii Rehabilitation

Rehabilitation (supervised formal therapy) required as a result of a work-related injury should be focused on restoring functional ability required to meet the patient’s daily and work activities and return to work; striving to restore the injured worker to pre-injury status in so far as is feasible.

Active therapy requires an internal effort by the patient to complete a specific exercise or task. Passive therapy are those interventions not requiring the exertion of effort on the part of the patient, but rather are dependent on modalities delivered by a therapist. Generally passive interventions are viewed as a means to facilitate progress in an active therapy program with concomitant attainment of objective functional gains. Active interventions should be emphasized over passive interventions.

The patient should be instructed to continue both active and passive therapies at home as an extension of the treatment process in order to maintain improvement levels.

Assistive devices may be included as an adjunctive measure incorporated into the rehabilitation plan to facilitate functional gains.

C.1.c.iii.a Therapeutic Exercise – Physical / Occupational Therapy

**Recommended** to improve function, including range of motion and strength.

*Frequency/Dose/Duration:* Total numbers of visits may be as few as two to three for patients with mild functional deficits or up to 12 to 15 with more severe deficits with documentation of ongoing objective functional improvement.

When there are ongoing functional deficits, more than 12 to 15 visits may be indicated if there is documentation of functional improvement towards specific objective functional goals (e.g., range of motion, advancing ability to perform work activities). As part of the rehabilitation plan a home exercise program should be developed and performed in conjunction with the therapy.

*Indications for Discontinuation:* Resolution of achilles tendinopathy pain, intolerance, lack of efficacy or noncompliance.

Evidence for the Use of Exercise for Achilles Tendinopathy

C.1.c.iii.b Extracorporeal Shockwave Therapy for Chronic Mid-portion Achilles Tendinopathy
**Recommended** - as an adjunct to an eccentric exercise for chronic, recalcitrant Achilles tendinopathy.

**Indications**: Moderate to severe, recalcitrant Achilles tendinopathy. Patients should have failed NSAIDs, eccentric exercises, therapy, and local injection(s).

**Frequency/Duration**: Three to four weekly sessions over three to four consecutive weeks.

**Indications for Discontinuation**: Completion of course, resolution of symptoms, adverse effects, intolerance, noncompliance.

C.1.c.iii.c  **Extracorporeal Shockwave Therapy for Acute, Subacute, or Postoperative Achilles Tendinopathy**

**Not Recommended** - for treatment of acute, subacute, or postoperative Achilles tendinopathy.

**Evidence for the Use of Extracorporeal Shockwave Therapy for Achilles Tendinopathy**

C.1.c.iii.d  **Acupuncture for Acute, Subacute, Chronic, or Postoperative Achilles Tendinopathy**

**Not Recommended** - for the treatment of acute, subacute, chronic, or postoperative Achilles tendinopathy.

C.1.c.iii.e  **Dry Needling for Acute, Subacute, or Chronic Achilles Tendinopathy**

**Not Recommended** - for treatment of acute, subacute, or chronic Achilles tendinopathy.

**Rationale for Recommendation**: As there are other effective treatments, dry needling is not recommended for treatment of Achilles tendinopathy.

C.1.c.iii.f  **Massage and Tendon Mobilization for Acute, Subacute, Chronic, or Postoperative Achilles Tendinopathy**

**Not Recommended** - for treatment of acute, subacute, chronic, or postoperative Achilles tendinopathy.

C.1.c.iii.g  **Therapeutic Ultrasound for Acute, Subacute, Chronic, or Postoperative Achilles Tendinopathy**

**Not Recommended** - for treatment of acute, subacute, chronic, or postoperative Achilles tendinopathy.
C.1.c.iii.h Iontophoresis with Glucocorticosteroid for Acute, Subacute, or Chronic Achilles Tendinopathy

**Recommended** - for treatment of acute, subacute, or chronic Achilles tendinopathy.

*Indications*: Acute, subacute, or chronic Achilles tendinopathy.

*Frequency/Duration*: Four treatments over two weeks with dexamethasone or other glucocorticoid. Therapy should include a concurrent eccentric exercise program.

*Indications for Discontinuation*: Resolution, adverse effects, intolerance, noncompliance.

C.1.c.iii.i Iontophoresis with Glucocorticosteroid for Postoperative Achilles Tendinopathy

**Not Recommended** - for treatment of postoperative Achilles tendinopathy.

C.1.c.iii.j Iontophoresis with NSAIDs for Acute, Subacute, Chronic, or Postoperative Achilles Tendinopathy

**Not Recommended** - for treatment of acute, subacute, chronic, or postoperative Achilles tendinopathy.

*Rationale for Recommendations*: Although evidence is minimal for efficacy in acute and subacute Achilles tendinopathy, iontophoresis with glucocorticosteroids is recommended for acute, subacute, or chronic Achilles tendinopathy, although the treatment has not been specifically tested among those patients.

*Evidence for the Use of Iontophoresis for Achilles Tendinopathy*

C.1.c.iii.k Phonophoresis for Acute, Subacute, Chronic, or Postoperative Achilles Tendinopathy

**Not Recommended** - for treatment of acute, subacute, chronic, or postoperative Achilles tendinopathy.

C.1.c.iii.l Low-level Laser Therapy for Select Chronic Achilles Tendinopathy

**Recommended** - for treatment of select patients with chronic Achilles tendinopathy.
Indications: Chronic Achilles tendinopathy; patients should generally have failed NSAIDs, eccentric exercises, iontophoresis, and injection(s).

Frequency/Duration: Twelve sessions over eight weeks. Therapy should include a concurrent active therapeutic exercise program.

Indications for Discontinuation: Resolution, adverse effects, intolerance, noncompliance.

C.1.c.iii.m Low-level Laser Therapy for Acute, Subacute, or Postoperative Achilles Tendinopathy

Not Recommended - for treatment of acute, subacute, or postoperative Achilles tendinopathy.

Evidence for the Use of Low-level Laser Therapy for Achilles Tendinopathy

C.1.c.iv Injection Therapy

C.1.c.iv.a Glucocorticosteroid Injections (Low-Dose) for Paratendon Bursitis

Recommended - as therapy for treatment paratendon bursitis.

Indications: Treatment with other interventions such as NSAIDs and exercises should have been attempted previously and either failed or results were unsatisfactory.

Frequency/Duration: Up to three injections of glucocorticosteroid over three weeks, with second and third injections performed if the first provides decrease in pain and increased function.

Indications for Discontinuation: Resolution, intolerance, adverse effects, or lack of benefits.

C.1.c.iv.b Glucocorticosteroid Injections (Low-Dose) for Acute, Subacute, Chronic or Postoperative Achilles Tendinopathy

Not Recommended - for treatment of acute, subacute, chronic or postoperative Achilles tendinopathy.

Evidence for the Use of Glucocorticosteroid Injections

C.1.c.iv.c Platelet Rich Plasma Injections for Achilles Tendinopathy

Not Recommended - for treatment of Achilles tendinopathy.
Evidence for the Use of Platelet Rich Plasma

C.1.c.iv.d Glycosaminoglycan Polysulfate Local Injection (GAGPS) for Acute, Subacute, or Postoperative Achilles Tendinopathy

Not Recommended - for treatment of acute, subacute, or postoperative Achilles tendinopathy.

Rationale for Recommendations: There is limited evidence that GAGPS may be beneficial for patients with chronic symptoms of Achilles tendon conditions.

Evidence for the Use of Glycosaminoglycan Injections

C.1.c.iv.e Subcutaneous Heparin Injection for Acute, Subacute, or Chronic Achilles Tendinopathy

Not Recommended - for treatment of acute, subacute, or chronic Achilles tendinopathy.

Evidence for the Use of Heparin Injections

Actovegin Injections
Actovegin injection (deproteinized hemodialysate from calf blood) into the paratendon for acute and chronic mid-portion Achilles tendinopathy.

C.1.c.iv.f Actovegin Injection for Acute, Subacute, or Chronic Achilles Tendinopathy

Not Recommended - for the treatment of acute, subacute or chronic Achilles tendinopathy.

Evidence for the Use of Actovegin Injections

C.1.c.iv.g Prolotherapy, including Polidocanol and Hypertonic Glucose Injections for Acute, Subacute, Chronic or Postoperative Achilles Tendinopathy

Not Recommended - for the treatment of most acute, subacute or chronic and postoperative Achilles Tendinopathy.

Evidence for the Use of Polidocanol Injections

C.1.c.iv.h Apoprotinin Injection for Acute, Subacute, or Chronic Achilles Tendinopathy

Not Recommended - for treatment of acute, subacute, or chronic Achilles tendinopathy.

Evidence for the Use of Apoprotinin Injections
C.1.c.iv High-volume Image-guided Injection for Chronic Achilles Tendinopathy

**Not Recommended** - for treatment of chronic Achilles Tendinopathy.

C.1.c.v Surgery

C.1.c.v.a Surgery for the Treatment of Chronic Achilles Tendinopathy without Rupture

**Recommended** - for select cases of chronic Achilles tendinopathy without rupture.

*Indications:* Patients with moderate to severe chronic Achilles tendinopathies who have failed multiple non-surgical treatments and whose condition has lasted at least six months. Patients should generally have failed NSAID(s), eccentric exercises, iontophoresis, injection(s) and low level laser therapy.

C.1.c.v.b Surgery for the Treatment of Acute or Subacute Achilles Tendinopathy Without Rupture

**Not Recommended** - for acute or subacute Achilles tendinopathy without rupture.

*Rationale for Recommendations:* Surgery is not recommended until a course of at least six months of other non-operative treatments with demonstrated efficacy has been attempted and the patient’s symptoms are sufficient to warrant the risks of surgical intervention.

C.1.c.vi Other

C.1.c.vi.a Orthotic Devices (Such as Heel Lifts, Heel Pads or Heel Braces) for Acute, Subacute, Chronic, or Postoperative Achilles Tendinopathy

**Not Recommended** - for treatment of acute, subacute, or chronic Achilles tendinopathy.

*Evidence for the Use of Orthotic Devices for Achilles Tendinopathy*

---

C.2 Achilles Tendon Rupture

The cardinal symptom of an Achilles tendon rupture is a sudden pain in the posterior heel that is often accompanied by a “pop” heard emanating from the heel. There is generally no history of prior symptoms (pain, stiffness) prior to rupture.
Diagnosis of an Achilles tendon rupture is most often based on loss of plantar flexion strength, palpation of a gap in the mid-portion of the tendon (proximal to the calcaneal insertion), and a positive squeeze test of the calf muscle that fails to elicit plantar flexion. Specific imaging is not required for most acute rupture cases.

There are no other specific diagnostic criteria for Achilles tendon rupture. Acute rupture refers to rupture that presents for evaluation within four weeks, whereas chronic rupture refers to ruptures that present for evaluation four to six weeks or more after an acute injury.

Upon establishment of the diagnosis, initial treatment is symptomatic until the definitive care plan is established. This may include immobilization, relative rest, NSAIDs, acetaminophen and cryotherapy.

C.2.a Diagnostic Studies

Diagnosis of an Achilles tendon rupture is generally made through clinical history and physical examination findings.

X-ray is generally not used for the diagnosis of acute Achilles rupture, although it may be helpful in identifying tendon calcification.

C.2.a.i Routine X-ray for Diagnosis of Acute Achilles Rupture

Not Recommended - to diagnose acute Achilles tendon rupture.

Indications: Achilles tendon ruptures resulting from direct trauma or if suspected rupture involves the calcaneal insertion, or among patients with reasonable suspicion of tendon calcification. Ruptures of the tendon at the calcaneal insertion are reported to be rare, although if suspected radiography may detect avulsion of the bony insertion.

C.2.a.ii Ultrasound for Diagnosis of Acute Achilles Tendon Rupture

Recommended - for the diagnosis of acute Achilles tendon rupture.

Indications: Clinical suspicion of rupture is high but uncertain.

Rationale for Recommendation: It is recommended as the main confirmatory diagnostic test for Achilles ruptures, particularly when there is diagnostic uncertainty.

C.2.a.iii MRI for Diagnosis of Acute Achilles Tendon Rupture

Recommended - for the evaluation of acute Achilles tendon rupture.

Indications: Clinical suspicion of rupture is high but uncertain.

Rationale for Recommendation: MRI is recommended for select use as an alternative when clinical suspicion for rupture is high. It is sometimes used to evaluate the Achilles tendon particularly where there is diagnostic uncertainty, although ultrasound has been generally preferred.
C.2.b Medications

For most patients, ibuprofen, naproxen, or other older generation nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence suggests acetaminophen is modestly less effective. There is evidence that NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.

C.2.b.i NSAIDs for Treatment of Acute, Subacute, Chronic, or Postoperative Achillies Tendon Rupture pain

**Recommended** - for treatment of acute, subacute, chronic, or postoperative Achillies tendon rupture pain.

*Indications:* For acute, subacute, chronic, or postoperative Achillies tendon rupture, NSAIDs are recommended for treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

*Frequency/Duration:* As needed use may be reasonable for many patients.

*Indications for Discontinuation:* Resolution of foot/ankle pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.

C.2.b.ii NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding

**Recommended** concomminent use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine Type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

*Indications:* For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.

*Frequency/Dose/Duration:* Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding.

*Indications for Discontinuation:* Intolerance, development of adverse effects, or discontinuation of NSAID.

C.2.b.iii NSAIDs for Patients at Risk for Cardiovascular Adverse Effects

Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.
**Recommended** - Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse.

**Recommended** - If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to minimize the potential for the NSAID to counteract the beneficial effects of aspirin, the NSAID should be taken at least 30 minutes after or eight hours before the daily aspirin.

### C.2.b.iv Acetaminophen for Treatment of Acute, Subacute, or Chronic Achilles Rupture Pain

**Recommended** for treatment of acute, subacute, or chronic Achilles rupture pain, particularly in patients with contraindications for NSAIDs.

**Indications:** All patients with foot/ankle pain, including acute, subacute, chronic, and postoperative.

**Dose/Frequency:** Per manufacturer’s recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

**Indications for Discontinuation:** Resolution of pain, adverse effects or intolerance.

### C.2.b.v Opioids for Pain from Acute or Postoperative Achilles Tendon Repair

**Recommended** limited use of opioids (not to exceed seven days) for the treatment of acute Achilles tendon rupture is a treatment option for select patients presenting with acute or moderate to severe pain related to Achilles rupture. Limited use of opioids for a few days (not to exceed seven days) is also recommended for select patients who have undergone recent Achilles tendon repair or those who encountered surgical complications.

**Indications:** Acute rupture or postoperative pain management for patients with moderate to severe pain.

**Frequency/Dose/Duration:** Frequency and dose per manufacturer’s recommendations; may be taken scheduled or as needed; generally taken for short courses of a few days, with subsequent weaning to nocturnal use if needed, then discontinuation. Total length of treatment usually ranges from a few days to one week. Generally should be utilized to supplement pain relief in addition to an NSAID or acetaminophen to reduce total need for opioid and the consequent adverse effects.

**Indications for Discontinuation:** Sufficient pain management with other methods such as NSAIDs, resolution of pain, intolerance, adverse effects, lack of benefits, or failure to progress over a couple weeks.
Rationale for Recommendations: Opioids are recommended for brief select use in postoperative patients with primary use at night to facilitate adequate postoperative sleep.

C.2.b.vi Opioids for Pain from Subacute or Chronic Achilles Tendon Repair

Not Recommended for treatment of pain from subacute or chronic Achilles tendon repair.

Rationale for Recommendation: Opioids are not recommended for routine use.

C.2.b.vii Prophylaxis for Prevention of Deep Venous Thrombosis

Recommended - for the prevention of deep venous thrombosis.

Indications – Patients with predisposing risks for developing venous thrombosis events. High-risk populations are not well defined currently, and therefore require a high degree of physician and patient judgment. A low threshold for prophylaxis may be appropriate for patients with prior history of thrombolic and thromboembolic events, delayed rehabilitation or ambulation, obesity, diabetes, or other coagulation disorders.

C.2.b.viii Thrombosis Prophylaxis for Prevention of Deep Venous Thrombosis

Not Recommended to prevent deep venous thrombosis.

Evidence for the Use of DVT Prophylaxis for Achilles Tendon Rupture Repair

C.2.c Treatments

C.2.c.i Cryotherapy / Heat

C.2.c.i.a Self-application of Cryotherapy or Heat Therapy for Acute, Subacute, Chronic, or Postoperative Achilles Tendon Rupture

Recommended - for treatment of acute, subacute, chronic, or postoperative Achilles tendon rupture.

Indications: Acute, subacute, chronic, or postoperative patients with Achilles tendon rupture.

Frequency/Duration: Approximately three to five self-applications per day as needed.

Indications for Discontinuation: Resolution, adverse effects, noncompliance.

Rationale for Recommendation: Ice may be of short-term benefit in reducing swelling and pain for acute rupture. Heat
may be helpful for healing for a few days after the rupture or surgery.

C.2.c.ii  Rehabilitation

Therapy

Rehabilitation (supervised formal therapy) required as a result of a work-related injury should be focused on restoring functional ability required to meet the patient’s daily and work activities and return to work; striving to restore the injured worker to pre-injury status in so far as is feasible.

Active therapy requires an internal effort by the patient to complete a specific exercise or task. Passive therapy are those interventions not requiring the exertion of effort on the part of the patient, but rather are dependent on modalities delivered by a therapist. Generally passive interventions are viewed as a means to facilitate progress in an active therapy program with concomitant attainment of objective functional gains. Active interventions should be emphasized over passive interventions.

The patient should be instructed to continue both active and passive therapies at home as an extension of the treatment process in order to maintain improvement levels.

Assistive devices may be included as an adjunctive measure incorporated into the rehabilitation plan to facilitate functional gains.

C.2.c.ii.a  Therapeutic Exercise - Physical / Occupational Therapy

**Recommended** – to improve function, including range of motion and strength.

*Frequency/Dose/Duration:* Frequency of visits is usually individualized based on severity of the limitation. Two to three visits per week for two weeks are often used to initiate an exercise program. Total numbers of visits may be as few as two to three for mild patients or up to 12 to 15 with documentation of objective functional improvement.

As part of the rehabilitation plan, patients should be instructed to continue both active and passive therapy, at home as an extension of the treatment process in order to maintain improvement.

*Indications:* All postoperative and conservatively managed Achilles rupture patients.

*Indications for Discontinuation:* Resolution of pain, intolerance, lack of efficacy or noncompliance.

C.2.c.ii.b  Postoperative TENS for Achilles Tendon Repair
**Not Recommended** - as a postoperative treatment for Achilles tendon rupture.

*Rationale for Recommendation*: There is no defined benefit of TENS for promoting the healing process.

**C.2.c.iii Surgery**

**C.2.c.iii.a Surgery for Treatment of Achilles Tendon Rupture**

**Recommended** - for treatment of ruptured Achilles tendon. The mixed results of the data supporting operative and non-operative care should be discussed with patients when covering treatment options. Discussion should include the equivocal superiority of surgical compared to non-operative treatment.

**C.2.c.iii.b Non-Operative Management of Achilles Tendon Rupture with Functional Splinting and Casting**

**Recommended** - for Achilles tendon rupture. Non-operative management may be indicated in many cases, particularly for select patients with low physical demands where risk factors may outweigh benefits.

*Evidence for the Use of Non-operative and Surgical Repair for Achilles Tendon Rupture*

**Surgical Repair - Open and Percutaneous Methods**

Surgical repairs have included two basic approaches – open and percutaneous methods.

**C.2.c.iii.c Open and Percutaneous Operative Approaches**

**Recommended** - for patients undergoing operative repair. There is no recommendation of one approach over the other.

**C.2.c.iii.d Augmented Surgical Repair for Acute Ruptures**

**Not Recommended** - for acute ruptures unless primary repair is not possible.

**C.2.c.iii.e Augmented Surgical Repair for Chronic or Neglected Ruptures**

**Not Recommended** - for chronic or neglected ruptures.

*Evidence for the Use of Surgical Technique for Achilles Tendon Rupture*

**C.2.c.iii.f Early Weight Bearing for Postoperative Rehabilitation of Achilles Tendon Repair**
**Recommended** - as a primary treatment method for postoperative rehabilitation of Achilles tendon ruptures for functional bracing or rigid immobilization.

*Indications:* All postoperative nonaugmented Achilles tendon repairs concomitant with functional bracing or rigid casting.

*Frequency/Duration:* Initiate postoperative to two weeks.

*Indications for Discontinuation:* Rerupture, surgical complications, physical ability.

*Rationale for Recommendation:* There is strong evidence that early immobilization is beneficial for short-term functional recovery, may result in increased mobility of the patient with improved quality of life, and has no demonstrated increase in complication rates.

C.2.c.iii.g  **Functional Bracing for Postoperative Rehabilitation of Achilles Tendon Repair**

**Recommended** - as a primary treatment method for postoperative care of Achilles tendon ruptures.

*Indications:* All postoperative Achilles tendon repairs.

*Frequency/Duration:* Apply zero to two weeks postoperative.

*Indications for Discontinuation:* Discomfort, noncompliance, device intolerance.

Evidence for the Use of Postoperative Management for Achilles Tendon Rupture

### C.3 Ankle Tendinopathies (Other than Achilles Tendinopathy)

The ankle’s tendinous compartments are susceptible to stenosing tenosynovitis, similar to those of the wrist. They may be affected by disease (e.g., rheumatic disorders, diabetes mellitus, and infection) and undergo age-related degenerative changes. Tendon subluxations, dislocations, and tears occur. There are no quality trials addressing ankle tendinopathies other than Achilles tendinopathy. Guidance for these ankle-foot tendon disorders is based on analogies to other tendinopathies, particularly of the wrist.
C.4  Tenosynovitis (Including Stenosing Tenosynovitis)

Patients with tendinopathy present with localized ankle pain that is augmented by movement. Occasionally, pain may extend along the affected tendon sheath.

Initial care usually involves limitation of the physical factors thought to be contributing. Walking casts or boots, splints, or braces for tendinoses may be helpful especially in moderate to severe cases. NSAIDs are often prescribed for initial treatment.

C.4.a  Diagnostic Studies

There are no tests that are typically performed for tenosynovitis. X-rays are usually not helpful. Boney deformities may contribute to the tenosynovitis and occult fractures may occur.

C.4.b  Medications

For most patients, ibuprofen, naproxen, or other older generation nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence suggests acetaminophen is modestly less effective. There is evidence that NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.

C.4.b.i  Non-Steroidal Anti-inflammatory Drugs (NSAIDs) for Acute, Subacute or Chronic Ankle Tenosynovitis

**Recommended** - for treatment of acute, subacute, or chronic ankle tenosynovitis.

*Indications*: For acute, subacute, chronic, or postoperative ankle compartment tenosynovitis, NSAIDs are recommended for treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

*Frequency/Duration*: As needed use may be reasonable for many patients.

*Indications for Discontinuation*: Resolution of foot/ankle pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.

C.4.b.ii  NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding

**Recommended** – concommitant use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

*Indications*: For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk
patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.

*Frequency/Dose/Duration:* Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding.

*Indications for Discontinuation:* Intolerance, development of adverse effects, or discontinuation of NSAID.

**C.4.b.iii NSAIDs for Patients at Risk for Cardiovascular Adverse Effects**

Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.

**Recommended** - Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse.

**Recommended** - If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to minimize the potential for the NSAID to counteract the beneficial effects of aspirin, the NSAID should be taken at least 30 minutes after or eightours before the daily aspirin.

*Evidence for the Use of NSAIDs for Compartment Tenosynovitis*

**C.4.b.iv Acetaminophen for Tenosynovitis Pain**

**Recommended** - for treatment of acute, subacute, or chronic Achilles Tenosynovitis Pain, particularly in patients with contraindications for NSAIDs.

*Indications:* All patients with foot/ankle pain, including acute, subacute, chronic, and postoperative.

*Dose/Frequency:* Per manufacturer’s recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

*Indications for Discontinuation:* Resolution of pain, adverse effects or intolerance.

**C.4.c Treatments**

**C.4.c.i Mobilization / Immobilization**

**C.4.c.i.a Walking Boots, Casts, Splints, and Braces for Acute and Subacute Ankle Tenosynovitis**

**Recommended** - for treatment of acute and subacute ankle tendinoses.
Indications: Patients with tendinosis.

Frequency/Duration: Worn while ambulating.

Indications for Discontinuation: Failure to respond or resolution.

C.4.c.ii Rehabilitation

Rehabilitation (supervised formal therapy) required as a result of a work-related injury should be focused on restoring functional ability required to meet the patient’s daily work activities and return to work; striving to restore the injured worker to pre-injury status in so far as is feasible.

Active therapy requires an internal effort by the patient to complete a specific exercise or task. Passive therapy are those interventions not requiring the exertion of effort on the part of the patient, but rather are dependent on modalities delivered by a therapist. Generally passive interventions are viewed as a means to facilitate progress in an active therapy program with concomitant attainment of objective functional gains. Active interventions should be emphasized over passive interventions.

The patient should be instructed to continue both active and passive therapies at home as an extension of the treatment process in order to maintain improvement levels.

Assistive devices may be included as an adjunctive measure incorporated into the rehabilitation plan to facilitate functional gains.

C.4.c.ii.a Therapy to Address Residual Deficits, Particularly Postoperatively

Recommended – for the treatment of residual deficits associated with acute, subacute, chronic, or postoperative tenosynovitis.

Frequency/Dose/Duration – Total numbers of visits may be as few as two to three for patients with mild functional deficits or up to 12 to 15 with more severe deficits with documentation of ongoing objective functional improvement.

When there are ongoing functional deficits, more than 12 to 15 visits may be indicated if there is documentation of functional improvement towards specific objective functional goals (e.g., range of motion, advancing ability to perform work activities). As part of the rehabilitation plan a home exercise program should be developed and performed in conjunction with the therapy.

Indications for Discontinuation: Resolution of pain, intolerance, lack of efficacy or noncompliance.
C.4.c.ii.b  Other Non-Operative Interventions Including Manipulation and Mobilization, Massage, Deep Friction Massage, or Acupuncture for Acute, Subacute, or Chronic Ankle Tenosynovitis

**Not Recommended** - for the treatment of acute, subacute, or chronic ankle tenosynovitis.

C.4.c.ii.c  Iontophoresis for Acute and Subacute Ankle Tenosynovitis

**Recommended** - for ankle tenosynovitis using glucocorticosteroids and sometimes NSAIDs.

*Indications:* Patients with ankle tendinosis. Generally those who either fail to respond adequately to NSAIDs, splints, and activity modifications or decline injection.

*Dose:* Glucocorticosteroid is generally used.

*Frequency/Duration:* Generally two to three treatments to ascertain efficacy; an additional four to six treatments may be scheduled if efficacious. If improvements continue at six appointments, an additional four to six treatments are reasonable.

*Indications for Discontinuation:* Failure to respond, development of adverse effects, resolution.

*Rationale for Recommendation:* Iontophoresis with either a glucocorticoid or NSAID is recommended for select patients who fail to respond to other treatments or who decline injection.

C.4.c.iii  Injection Therapy

C.4.c.iii.a  Glucocorticosteroid Injections for Acute, Subacute, or Chronic Ankle Tendinosis

**Recommended** - for treatment of acute, subacute, or chronic ankle tendinosis.

*Indications:* Ankle symptoms of pain over a compartment. Generally, at least one week of non-invasive treatment to determine if condition will resolve without invasive treatment. It is reasonable to treat cases with an initial injection. An adjuvant injectable anesthetic is typically used.

*Frequency/Duration:* It is recommended that a single injection be scheduled, and the results evaluated to document improvement. Failure of a response within one to two weeks should result in reanalysis of the diagnosis and
consideration of repeat injection. Recurrence of symptoms months later should result in consideration of re-injection. Repeat injections can be considered when there is decreased pain and increased function from the previous injection. More than three injections in a year should be avoided due to tendon weakening and risk of rupture. Recurring injections on a year after year basis should also be similarly avoided.

*Indications for Discontinuation:* If a partial response, consideration should be given to repeating the injection, typically at a modestly higher dose.

*Evidence for the Use of Glucocorticosteroid Injections for Ankle Tendinoses*

C.4.c.iv  **Surgery**

C.4.c.iv.a  **Surgical Release for Subacute or Chronic Ankle Tenosynovitis**

*Not Recommended* - for patients with subacute or chronic ankle tenosynovitis who fail to respond to non-operative interventions including injections.

---

### C.5 Plantar Heel Pain (“Plantar Fasciitis”)

Heel pain is the most common area of pain in the foot. Plantar heel pain, known as “plantar fasciitis,” is common. Other names for plantar heel pain include painful heel syndrome, heel spur syndrome, runner’s heel, subcalcaneal pain, calcaneodynia, plantar fasciopathy, and calcaneal periostitis. Plantar fasciitis is usually marked pain in the inferior or plantar aspect of either the center or medial heel. Pain may be reported distal towards the arch of the foot. As noted, it is most noticeable during weight-bearing activities, especially the first weight-bearing step of the day or after periods of sitting or recumbency.

Plantar fasciitis generally responds well to conservative management, with more than 90% of patients resolving over a six to 12 month period with non-surgical intervention.

Initial management of plantar heel pain is non-invasive. More than 90% of plantar heel pain will resolve with non-invasive measures over a six to 12 month period. Possibly, the most important non-operative treatment is reassuring the patient that 95% of those with plantar fasciitis will have resolution of symptoms in 12 to 18 months.

*Plantar Fasciitis Diagnostic Criteria (Appendix D.2 – Table 3)*

#### C.5.a Diagnostic Studies

Imaging plays a limited role in routine clinical practice and is generally reserved for select cases to rule out other causes of heel pain or to establish the diagnosis of plantar fasciitis when it is in doubt.
Plain radiographs are utilized for diagnosing plantar fasciitis.

C.5.a.i Use of X-Ray for Diagnosis of Plantar Heel Pain

**Recommended** – for diagnosing suspected fracture in patients with plantar heel pain.

*Indication*: Evaluation of plantar heel pain when calcaneal fracture or osseous tumor is suspected, or to rule out other causes of heel pain. Plain films should not be obtained solely to identify the presence of heel spurs.

C.5.a.ii MRI for Diagnosis of Select Patients with Plantar Fasciitis

**Recommended** - for the evaluation of select patients with plantar fasciitis.

*Indications*: Suspected plantar fascial rupture, avascular necrosis of talar dome, and stress fracture of the talar neck particularly if heel pain is not improving.

*Rationale for Recommendation*: MRI may be useful in the diagnosis of causes of heel pain other than plantar fasciitis, including calcaneal stress fracture, plantar fascia rupture, perifascial fluid, calcaneal spurs, avascular necrosis of talar dome, joint fluid, ganglion cyst, stress fracture of the talar neck, and osseous tumors.

*Evidence for the Use of MRI for Plantar Fasciitis*

C.5.a.iii SPECT-CT for Diagnosis of Plantar Fasciitis

**Not Recommended** - for the diagnosis of plantar heel pain.

C.5.a.iv Ultrasound for Diagnosis of Plantar Fasciitis

**Recommended** - for the evaluation of select patients with plantar fasciitis.

*Indications*: Evaluation of plantar heel pain when clinical diagnosis is uncertain or after no improvement from a course of conservative treatment of four to six weeks.

*Rationale for Recommendation*: is recommended for cases of suspected plantar fascial rupture or plantar calcaneal bursitis if symptoms are not resolved after a trial of non-invasive therapy.

C.5.b Medications

For most patients, ibuprofen, naproxen, or other older generation nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence
suggests acetaminophen is modestly less effective. There is evidence that NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.

C.5.b.i Non-steroidal Anti-inflammatory Drugs (NSAIDs)
NSAIDs for Treatment of Acute, Subacute, Chronic, or Postoperative Plantar Fasciitis Pain

**Recommended** - for treatment of acute, subacute, chronic, or postoperative plantar fasciitis pain.

*Indications:* For acute, subacute, chronic, or postoperative plantar fasciitis pain, NSAIDs are recommended for treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

*Frequency/Duration:* As needed use may be reasonable for many patients.

*Indications for Discontinuation:* Resolution of foot/ankle pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.

C.5.b.ii NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding

**Recommended** – concomitant use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine Type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

*Indications:* For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.

*Frequency/Dose/Duration:* Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding.

*Indications for Discontinuation:* Intolerance, development of adverse effects, or discontinuation of NSAID.

C.5.b.iii NSAIDs for Patients at Risk for Cardiovascular Adverse Effects
Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.

**Recommended** - Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse.

**Recommended** - If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to
minimize the potential for the NSAID to counteract the beneficial effects of aspirin, the NSAID should be taken at least 30 minutes after or eight hours before the daily aspirin.

C.5.b.iv Acetaminophen for Treatment of Plantar Fasciitis Pain

**Recommended** - for treatment of acute, subacute, or chronic Plantar Fasciitis Pain, particularly in patients with contraindications for NSAIDs.

*Indications:* All patients with foot/ankle pain, including acute, subacute, chronic, and postoperative.

*Dose/Frequency:* Per manufacturer’s recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

*Indications for Discontinuation:* Resolution of pain, adverse effects or intolerance.

*Evidence for the Use of NSAIDs and Acetaminophen for Plantar Fasciitis*

C.5.b.v Infliximab for Acute, Subacute, or Chronic Plantar Fasciitis

**Not Recommended** - for the treatment of acute, subacute, or chronic plantar fasciitis.

*Evidence for the Use of Infliximab for Plantar Fasciitis*

C.5.b.vi Opioids for Acute, Subacute, or Chronic Plantar Fasciitis Pain

**Not Recommended** - for the treatment of acute, subacute, or chronic plantar fasciitis.

C.5.b.vii Opioids for Post Op Plantar Fasciitis

**Recommended** – for limited use for a few postoperative days (not to exceed seven) for select patients with plantar fasciitis.

*Indications:* Postoperative pain management.

*Frequency/Dose/Duration:* Frequency and dose per manufacturer's recommendations; may be taken as scheduled or as needed. Generally suggested to be taken for short courses (a few days), with subsequent weaning to nocturnal use if needed, then discontinued.

*Indications for Discontinuation:* Sufficient pain management with other methods such as NSAIDs and acetaminophen, resolution of pain, intolerance, adverse effects, lack of benefits, or failure to progress.

*Rationale for Recommendations:* There is no quality evidence for the use of opioids for the treatment of acute, subacute, or chronic plantar heel pain. The vast majority of patients with plantar fasciitis generally do
not have pain sufficient to merit trialing with the risks of opioids. They
are not recommended for routine use.

Some patients may have insufficient pain relief with NSAIDs, thus
judicious use of opioids in the immediate postoperative period may be
helpful, particularly for nocturnal use. Opioids are recommended for brief
select use in postoperative patients with primary use at night to achieve
postoperative sleep while not impairing early rehabilitation.

**Evidence for the Use of Opioids for Plantar Fasciitis**

C.5.b.vii Oral or Intramuscular Glucocorticosteroids for Acute, Subacute, or
Chronic Plantar Heel Pain

**Not Recommended** - for the treatment of acute, subacute, or chronic
plantar heel pain.

*Rationale for Recommendation:* As evidence is lacking and evidence of
efficacy is present for several other treatments, the use of
glucocorticosteroids by oral or intramuscular routes is not
recommended.

**Evidence for the Use of Systemic Glucocorticosteroids for Plantar Heel Pain**

C.5.b.ix Vitamins for Treatment or Prevention of Plantar Fasciitis

**Not Recommended** - for the treatment or prevention of plantar fasciitis.

**Evidence for the Use of Vitamins for Plantar Fasciitis**

C.5.b.x Lidocaine Patches for Acute, Subacute, Chronic, or Postoperative
Plantar Fasciitis

**Not Recommended** - for the treatment of acute, subacute, chronic, or
postoperative plantar fasciitis.

**Evidence for the Use of Lidocaine Patch for Plantar Fasciitis**

C.5.b.xi Topical NSAIDs for Acute, Subacute, or Chronic Plantar Fasciitis
Pain

**Recommended** - for treatment of acute, subacute, or chronic plantar
fascial pain syndromes.

*Indications:* Mild, moderate, or severe plantar fasciitis or in patients with
contraindications for oral treatment. There is no evidence of comparative
superiority of one topical NSAID versus another.

*Frequency/Duration:* Frequency according to manufacturer’s
recommendation. Topical NSAIDs have been used for one to three
weeks.
Indications for Discontinuation: Resolution, intolerance, adverse effects, or lack of benefits.

Rationale for Recommendation: They are recommended for treatment of acute, subacute, and chronic plantar fascial or plantar heel pain, particularly in patients who do not tolerate or are poor candidates for oral treatment.

C.5.b.xii  Topical NSAIDs for Postoperative Plantar Fasciitis

Not Recommended - for postoperative plantar fasciitis.

Evidence for the Use of Topical NSAIDs for Plantar Fasciitis

C.5.c  Treatments

C.5.c.i  Cryotherapy / Heat

C.5.c.i.a  Cryotherapy for Acute, Subacute, Chronic, or Postoperative Plantar Heel Pain

Recommended - for treatment of acute, subacute, chronic, or postoperative plantar heel pain.

Indications: All patients with plantar heel pain.

Frequency/Duration: Approximately three to five self-applications per day as needed.

Indications for Discontinuation: Resolution, adverse effects, noncompliance.

C.5.c.i.b  Heat Therapy for Acute, Subacute, Chronic, or Postoperative Plantar Heel Pain

Recommended - for treatment of acute, subacute, chronic, or postoperative plantar heel pain.

Indications: All patients with plantar heel pain.

Frequency/Duration: Approximately three to five self-applications per day as needed.

Indications for Discontinuation: Resolution, adverse effects, noncompliance.

Rationale for Recommendations: Ice and heat may help particularly with more acute symptoms.

Evidence for the Use of Cryotherapy and Heat for Plantar Heel Pain
C.5.c.ii Mobilization / Immobilization

C.5.c.ii.a Casting for Chronic Plantar Fasciitis

**Not Recommended** - as a treatment for chronic plantar fasciitis.

Evidence for the Use of Casting for Plantar Fasciitis

C.5.c.ii.b Night Splints for Plantar Heel Pain

**Recommended** - for subacute or chronic plantar heel pain.

*Indications:* Subacute or chronic plantar fasciitis requiring temporary pain and stiffness improvement.

*Frequency/Duration:* Nightly for duration of effectiveness (as determined by improvement in symptoms and function while under the care of a health care provider).

*Indications for Discontinuation:* Resolution, adverse effects, intolerance, noncompliance.

Evidence for the Use of Night Splints for Plantar Heel Pain

C.5.c.iii Rehabilitation

Rehabilitation (supervised formal therapy) required as a result of a work-related injury should be focused on restoring functional ability required to meet the patient’s daily and work activities and return to work; striving to restore the injured worker to pre-injury status in so far as is feasible.

Active therapy requires an internal effort by the patient to complete a specific exercise or task. Passive therapy are those interventions not requiring the exertion of effort on the part of the patient, but rather are dependent on modalities delivered by a therapist. Generally passive interventions are viewed as a means to facilitate progress in an active therapy program with concomitant attainment of objective functional gains. Active interventions should be emphasized over passive interventions.

The patient should be instructed to continue both active and passive therapies at home as an extension of the treatment process in order to maintain improvement levels.

Assistive devices may be included as an adjunctive measure incorporated into the rehabilitation plan to facilitate functional gains.

C.5.c.iii.a Magnets for Acute, Subacute or Chronic Plantar Heel Pain

**Not Recommended** - for the treatment of acute, subacute, or chronic plantar heel pain.
Evidence for the Use of Magnets for Plantar Heel Pain

C.5.c.iii.b  Stretching Exercises for Plantar Fasciitis

**Recommended** - for treatment of plantar fasciitis.

*Indications:* Acute, subacute, or chronic plantar fasciitis.

*Frequency/Duration:* Ten-minute stretches three times a day; no limit identified for duration.

*Indications for Discontinuation:* Resolution, adverse effects, intolerance, noncompliance.

**Evidence for the Use of Stretching Exercises for Plantar Fasciitis**

C.5.c.iii.c  Heel Taping for Acute or Subacute Plantar Fasciitis or Heel Pain

**Recommended** - as a short-term treatment for acute or subacute plantar fasciitis or heel pain.

*Indications:* Patients with acute or subacute plantar fasciitis without adhesive allergies as a short-term intervention for pain relief.

*Frequency/Duration:* Daily application of tape for one to four weeks.

*Indications for Discontinuation:* Resolution, adverse effects, noncompliance, completion of four week course of treatment.

C.5.c.iii.d  Heel Taping for Chronic Plantar Fasciitis or Heel Pain

**Recommended** - for the treatment of chronic plantar fasciitis or heel pain.

*Rationale for Recommendations:* The efficacy of taping is limited to modest short-term pain relief. Taping is generally limited to short-term use because of its potential for skin sensitization and breakdown. The use of taping is recommended as a short-term strategy as an adjunct with other non-operative treatments.

**Evidence for the Use of Taping for Plantar Fasciitis**

C.5.c.iii.e  Acupuncture for Acute, Subacute, or Chronic Plantar Fasciitis
**Not Recommended** - treatment of acute, subacute, or chronic plantar fasciitis.

**Evidence for the Use of Acupuncture for Plantar Fasciitis**

**C.5.c.iii.f** Low Frequency Electrical Stimulation for Acute, Subacute, or Chronic Plantar Fasciitis

**Not Recommended** - for acute, subacute, or chronic plantar fasciitis.

**Evidence for the Use of Electrical Stimulation for Plantar Fasciitis**

**C.5.c.iii.g** Extracorporeal Shockwave Therapy for Chronic Plantar Fasciitis

**Recommended** - for chronic plantar fasciitis in select patients with chronic recalcitrant conditions.

*Indications*: Chronic plantar heel pain consistent with plantar fasciitis. In most studies of ESWT used for treatment of plantar fasciitis, patients often have at least six months of symptoms and fail therapy with active and passive exercises, NSAIDs, and glucocorticosteroid injection(s). The presence or absence of heel spur does not impact decision for use of ESWT.

*Frequency/Duration*: Treatment protocols vary; one to three treatment sessions with reported efficacy may be appropriate.

*Indications for Discontinuation*: Resolution, intolerance, noncompliance.

**C.5.c.iii.h** Extracorporeal Shockwave Therapy for Acute or Subacute Plantar Fasciitis

**Not Recommended** - for treatment of acute or subacute plantar fasciitis.

**C.5.c.iii.i** Ultrasound or Fluoroscopy Guidance for Shockwave Therapy for Plantar Fasciitis

**Not Recommended** - for treatment of plantar fasciitis.

**C.5.c.iii.j** Local Anesthesia with High Shockwave Therapy for Plantar Fasciitis

**Recommended** - in conjunction with high-energy ESWT for the treatment of plantar fasciitis.
C.5.c.iii.k Local Anesthesia with Low or Medium Shockwave Therapy for Plantar Fasciitis

**Not Recommended** - for the treatment of plantar fasciitis.

C.5.c.iii.l Radial Extracorporeal Shockwave Therapy for Chronic Plantar Fasciitis

**Not Recommended** - for the treatment of chronic plantar fasciitis.

C.5.c.iii.m Radial Extracorporeal Shockwave Therapy for Acute or Subacute Plantar Fasciitis

**Not Recommended** - for the treatment of acute or subacute plantar fasciitis.

Evidence for the Use of ESWT for Plantar Fasciitis

C.5.c.iii.n Iontophoresis with Glucocorticosteroid or Acetic Acid for Acute, Subacute, or Chronic Plantar Fasciitis

**Not Recommended** - for treatment of patients with acute, subacute, or chronic plantar fasciitis.

Evidence for the Use of Iontophoresis for Plantar Fasciitis

C.5.c.iii.o Low-level Laser Therapy for Acute, Subacute, or Chronic Plantar Fasciitis

**Not Recommended** - for treatment of acute, subacute, or chronic plantar fasciitis.

Evidence for the Use of Low-level Laser Therapy for Plantar Fasciitis

C.5.c.iii.p Manipulation for Acute, Subacute, Chronic, or Postoperative Plantar Heel Pain

**Not Recommended** - for treatment of acute, subacute, chronic, or postoperative plantar heel pain.

Evidence for the Use of Manipulation for Plantar Heel Pain

C.5.c.iii.q Massage and Soft Tissue Mobilization for Acute, Subacute, Chronic, or Postoperative Plantar Fasciitis

**Not Recommended** - for treatment of acute, subacute, chronic, or postoperative plantar fasciitis.

Evidence for the Use of Massage and Soft Tissue Mobilization for Plantar Fasciitis
C.5.c.iii.r  Phonophoresis for Acute, Subacute, Chronic, or Postoperative Plantar Heel Pain

*Not Recommended* - for treatment of acute, subacute, chronic, or postoperative plantar heel pain.

*Evidence for the Use of Phonophoresis for Plantar Heel Pain*

C.5.c.iii.s  Therapeutic Ultrasound for Acute, Subacute, Chronic, or Postoperative Plantar Fasciitis

*Not Recommended* - for treatment of acute, subacute, chronic, or postoperative plantar fasciitis.

*Evidence for the Use of Therapeutic Ultrasound for Plantar Fasciitis*

C.5.c.iii.t  Low-dose Radiation (Radiotherapy) for Chronic Plantar Heel Pain

*Not Recommended* - for treatment of chronic plantar heel pain.

*Evidence for the Use of Radiation Therapy for Plantar Heel Pain*

C.5.c.iv  Injection Therapy

C.5.c.iv.a  Autologous Blood Injection for Acute, Subacute, or Chronic Plantar Fasciitis

*Not Recommended* - for treatment of acute, subacute, or chronic plantar fasciitis.

*Evidence for the Use of Autologous Blood Injections for Plantar Fasciitis*

C.5.c.iv.b  Botulinum Toxin A Injection for Acute, Subacute or Chronic Plantar Fasciitis

*Not Recommended* - as a treatment for chronic plantar fasciitis.

*Evidence for the Use of Botulinum Toxin A Injections for Plantar Fasciitis*

C.5.c.iv.c  Glucocorticosteroid Injections for Chronic Plantar Fasciitis

*Recommended* - for short-term relief of chronic or recalcitrant plantar fasciitis.
Indications: Moderate or severe plantar fasciitis, failed stretching, exercise and other non-operative options.

Frequency/Duration: A second injection may be performed if the problem is incapacitating, other options have been exhausted, and the patient understands and accepts that rupture is a possible complication and will likely necessitate surgery.

Indications for Discontinuation: Resolution, intolerance, adverse effects, or lack of benefits.

C.5.c.iv.d Glucocorticosteroid Injections for Acute or Subacute Plantar Fasciitis

Not Recommended - for treatment of acute or subacute plantar fasciitis.

C.5.c.iv.e Guidance of Steroid Injection with Ultrasound or Scintigraphy

Not Recommended - compared with palpation.

Evidence for the Use of Injected Glucocorticosteroids for Plantar Fasciitis

C.5.c.iv.f Hyperosmolar Dextrose Injections for Plantar Fasciitis

Not Recommended - for treatment of plantar fasciitis.

Evidence for the Use of Hyperosmolar Dextrose for Plantar Fasciitis

C.5.c.iv.g Platelet Rich Plasma Injections for Plantar Fasciitis

Not Recommended - for treatment of plantar fasciitis.

Evidence for the Use of Platelet Rich Plasma for Plantar Fasciitis

C.5.c.v Surgery

C.5.c.v.a Surgery for Select Chronic Recalcitrant Plantar Fasciitis

Recommended - for select chronic recalcitrant plantar fasciitis. There is no recommendation for any particular procedure or method over another.

Indications: Moderate to severe chronic plantar fasciitis patients who have failed multiple non-surgical treatments and whose condition has lasted at least six to 12 months. Patients should generally have failed NSAID(s), plantar
Rationale for Recommendations: Surgery is recommended as an intervention after at least six months of other non-operative treatments have been attempted and the patient’s symptoms are sufficient to warrant the risks of surgical intervention. Patient education regarding suboptimal expected outcomes is recommended.

C.5.c.v.b Surgery for Acute or Subacute Plantar Fasciitis

Not Recommended - for treatment of acute or subacute plantar fasciitis.

Evidence for the Use of Surgery for Plantar Fasciitis

C.5.c.vi Other

C.5.c.vi.a Orthotic Devices for Acute, Subacute, or Chronic Plantar Heel Pain

Recommended - for treatment of acute, subacute, or chronic plantar heel pain.

Indications: Patients with plantar fasciitis.

Duration/Frequency: Daily use for two to three months.

Indications for Discontinuation: Resolution, adverse effects, noncompliance.

C.5.c.vi.b Custom Orthoses for Acute, Subacute, or Chronic Plantar Fasciitis

Not Recommended - for acute, subacute, or chronic plantar fasciitis.

C.5.c.vi.c Orthoses for Prevention of Plantar Fasciitis or Lower Extremity Disorders

Not Recommended - for the prevention of plantar fasciitis or lower extremity disorders.

Evidence for the Use of Orthoses for Plantar Fasciitis

C.5.c.vi.d Cryosurgery for Subacute, Acute or Chronic Plantar Heel Pain

Not Recommended - for treatment of chronic plantar heel pain.

Evidence for the Use of Cryosurgery for Plantar Fasciitis
C.5.c.vi.e Intracorporeal Pneumatic Shockwave Therapy (IPST) for Select Chronic Plantar Fasciitis

**Recommended** - for treatment of select chronic plantar fasciitis.

*Indications:* The use of IPST is recommended as an alternative to surgical intervention for recalcitrant plantar fasciitis among those patients who fail other non-operative treatments (i.e. NSAIDs, injection(s), stretching, other exercises and night splinting) and have a demonstrable heel spur.

*Evidence for the Use of Intracorporeal Pneumatic Shock Therapy for Plantar Fasciitis*

C.5.c.vi.f Percutaneous Calcaneus Fenestration for Chronic Plantar Heel Pain

**Not Recommended** - for treatment of chronic plantar heel pain.

*Evidence for the Use of Percutaneous Bone Fenestration for Plantar Heel Pain*

C.5.c.vi.g Radiofrequency Microtenotomy for Chronic Plantar Fasciitis

**Not Recommended** - for treatment of chronic plantar fasciitis.

*Evidence for the Use of Radiofrequency Microtenotomy for Plantar Fasciitis*

C.6 Foot Ulceration

C.6.a Physical Examination

The size, depth, location of and condition of the area surrounding an ulcer should be recorded. Check for exudate, odor, tunneling, undermining, sinus tracts, necrosis or eschar formation, infection, and signs of healing (granulation and epithelialization). Assess the wound margins and areas around the wound, including for induration, and tracking of infection or inflammation. Determine the stage of each ulcer.

Sensation of the foot and bone and joint deformities should be carefully assessed. Evaluation of perfusion of the foot and ankle, including dorsalis pedis and posterior tibial pulses, and of capillary refill is helpful. Footwear should be assessed for good repair, provision of comfort and support, and freedom from protruding, abrasive, or sharp features.
Wagner Grading System:
Grade 0 – No ulcer in a high-risk patient
Grade 1 – Superficial ulcer involving the full skin thickness but not underlying tissues
Grade 2 – Deep ulcer, penetrating down to ligaments and muscle, but no bone involvement or abscess formation
Grade 3 – Deep ulcer with cellulitis or abscess formation, often with osteomyelitis
Grade 4 – Localized gangrene
Grade 5 – Extensive gangrene involving the whole foot

C.6.b Diagnostic Studies

C.6.b.i X-Rays

Recommended - for those with questions of boney involvement, particularly concerns about osteomyelitis.

C.6.b.ii Bone Scans

Recommended – for those with question of boney involvement with indeterminate x-rays.

C.6.c Medications

Acetaminophen and/or non-steroidal anti-inflammatory drugs (NSAIDs) for pain control are often not needed due to the propensity for the joint to be denervated, but if needed are recommended.

For most patients, ibuprofen, naproxen, or other older generation NSAIDs are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence suggests acetaminophen is modestly less effective. There is evidence that NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.

C.6.c.i Non-Steroidal Anti-Inflammatory Drugs

Recommended - for treatment of acute, subacute, chronic, or postoperative non-healing and/or infected ulcers

Indications: For acute, subacute, chronic, or postoperative pain. NSAIDs are recommended for treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

Frequency/Duration: As needed use may be reasonable for many patients.

Indications for Discontinuation: Resolution of pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.
C.6.c.ii NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding

**Recommended** – concomimint use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine Type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

**Indications**: For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.

**Frequency/Dose/Duration**: Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding

**Indications for Discontinuation**: Intolerance, development of adverse effects, or discontinuation of NSAID.

C.6.c.iii NSAIDs for Patients at Risk for Cardiovascular Adverse Effects

Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.

**Recommended** - Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse.

**Recommended** - If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to minimize the potential for the NSAID to counteract the beneficial effects of aspirin, the NSAID should be taken at least 30 minutes after or eight hours before the daily aspirin.

C.6.c.iv Acetaminophen for Treatment of Acute, Subacute, or Chronic Non-Healing and/or Infected Ulcers

**Recommended** - for treatment of acute, subacute, or chronic pain, particularly in patients with contraindications for NSAIDs.

**Indications**: All patients with pain, including acute, subacute, chronic, and postoperative.

**Dose/Frequency**: Per manufacturer’s recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

**Indications for Discontinuation**: Resolution of pain, adverse effects or intolerance.
C.6.c.v  **Opioids for Pain from Acute, Subacute, Chronic or Postoperative Foot Ulcer**

*Recommended* - Limited use of opioids (not to exceed seven days) for the treatment of select patients presenting with severe pain related to foot ulcer. Limited use of opioids for a few days (not to exceed seven days) is also recommended for select patients who have undergone recent surgical intervention.

*Frequency/Dose/Duration:* Frequency and dose per manufacturer’s recommendations; may be taken scheduled or as needed; generally taken for short courses of a few days, with subsequent weaning to nocturnal use if needed, then discontinuation. Total length of treatment usually ranges from a few days to one week. Generally should be utilized to supplement pain relief in addition to an NSAID or acetaminophen to reduce total need for opioid and the consequent adverse effects.

*Indications for Discontinuation:* Sufficient pain management with other methods such as NSAIDs, resolution of pain, intolerance, adverse effects, lack of benefits, or failure to progress over a couple weeks.

C.6.c.vi  **Antibiotics**

*Recommended* – for most non-healing and/or infected ulcers. Antibiotic selection should be tailored to the cultured or anticipated organism.

C.6.d  **Treatments**

C.6.d.i  **Mobilization / Immobilization**

C.6.d.i.a  **Total Contact Casting for Foot Ulcers**

*Recommended* - for foot ulcers.

*Indications* – All patients with non-healing foot ulcerations are potential candidates.

*Evidence for the Use of Total Contact Casting*

C.6.d.i.b  **Foot Waffle Support Brace**

*Not Recommended* - for patients with foot ulcers.

*Evidence for the Use of the Foot Waffle Support Brace*

C.6.d.ii  **Surgery**

C.6.d.ii.a  **Surgical Debridement to Treat Lower Extremity Ulcers**

*Recommended* – for the treatment of lower extremity ulcers; particularly for devascularized, callus, wound edge tissue and foreign debris.
C.6.d.iii Other

C.6.d.iii.a Negative Pressure (Vacuum) Wound Care Systems

**Recommended** - for the treatment of chronic lower extremity ulcers.

*Indication*: Chronic, non-healing lower extremity ulcers.

C.6.d.iii.b Hyperbaric Oxygen for Foot Ulcers

**Recommended** - for treatment of select foot ulcers.

*Indications*: Wagner’s 2, 3, 4 foot ulcer(s) of more than three months duration.

*Frequency*: Treatments five days per week for eight weeks. May extend to ten weeks; maximum 40 treatments.

*Evidence for the Use of Hyperbaric Oxygen*

*Evidence for the Use of Negative Pressure Therapy (Vacuum Devices)*

C.7 Wound Care, Subungal Hematoma, Contusions

See Hand, Wrist, and Forearm guideline.

C.8 Charcot Joint (Neurogenic Arthropathy)

Refers to progressive degeneration of a weight bearing joint, a process marked by bony destruction, bone resorption, and eventual deformity due to loss of sensation secondary to neuropathy. Treatment includes addressing the underlying neuropathy.

C.8.a Diagnostic Studies

C.8.a.i X-Rays

**Recommended** – for diagnosing Charcot Joints.

C.8.a.ii MRIs

**Recommended** – to improve staging of Charcot joints.
**C.8.b Medications**

Acetaminophen and/or non-steroidal anti-inflammatory drugs (NSAIDs) for pain control are often not needed due to the propensity for the join to be denervated, but if needed are recommended.

For most patients, ibuprofen, naproxen, or other older generation NSAIDs are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence suggests acetaminophen is modestly less effective. There is evidence that NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.

### C.8.b.i NSAIDs for Treatment of Acute, Subacute, Chronic, or Postoperative Charcot Joint Pain

**Recommended** - for treatment of acute, subacute, chronic, or postoperative Charcot Joint pain.

**Indications:** For acute, subacute, chronic, or postoperative Charcot Joint pain, NSAIDs are recommended for treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

**Frequency/Duration:** As needed use may be reasonable for many patients.

**Indications for Discontinuation:** Resolution of foot/ankle pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.

### C.8.b.ii NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding

**Recommended** – concommient use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine Type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

**Indications:** For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.

**Frequency/Dose/Duration:** Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding.

**Indications for Discontinuation:** Intolerance, development of adverse effects, or discontinuation of NSAID.
C.8.b.iii  **NSAIDs for Patients at Risk for Cardiovascular Adverse Effects**

Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.

**Recommended** - Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse.

**Recommended** - If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to minimize the potential for the NSAID to counteract the beneficial effects of aspirin, the NSAID should be taken at least 30 minutes after or eight hours before the daily aspirin.

C.8.b.iv  **Acetaminophen for Treatment of Acute, Subacute, or Chronic Charcot Joint Pain**

**Recommended** - for treatment of acute, subacute, or chronic Charcot Joint Pain, particularly in patients with contraindications for NSAIDs.

**Indications:** All patients with joint pain, including acute, subacute, chronic, and postoperative.

**Dose/Frequency:** Per manufacturer’s recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

**Indications for Discontinuation:** Resolution of pain, adverse effects or intolerance.

C.8.c  **Treatments**

C.8.c.i  **Rehabilitation**

**Therapy**

Rehabilitation (supervised formal therapy) required as a result of a work-related injury should be focused on restoring functional ability required to meet the patient’s daily and work activities and return to work; striving to restore the injured worker to pre-injury status in so far as is feasible.

Active therapy requires an internal effort by the patient to complete a specific exercise or task. Passive therapy are those interventions not requiring the exertion of effort on the part of the patient, but rather are dependent on modalities delivered by a therapist. Generally passive interventions are viewed as a means to facilitate progress in an active therapy program with concomitant attainment of objective functional gains. Active interventions should be emphasized over passive interventions.
The patient should be instructed to continue both active and passive therapies at home as an extension of the treatment process in order to maintain improvement levels.

Assistive devices may be included as an adjunctive measure incorporated into the rehabilitation plan to facilitate functional gains.

C.8.c.i.a Gait Training

Recommended – for treatment of Charcot Joints.

C.8.c.i.b Splints, Walking Braces, Orthoses and Casts in Select Patients

Recommended – for treatment of Charcot Joints.

C.8.c.ii Surgery

C.8.c.ii.a Surgical Procedures Including Osteotomy May Be Performed to Address Deformities That Place the Foot at Risk of Ulceration

Recommended – to address deformities that place foot at risk of ulceration.

C.8.c.ii.b Open Reduction Internal Fixation of Fractures

Recommended – open reduction internal fixation of fractures.

C.8.c.ii.c Fusion of Charcot Joints in Select Patients

Recommended – fusion of Charcot Joints.

C.8.c.ii.d Arthroplasty (Total Joint Replacement) for Charcot Joints

Not Recommended – for Charcot Joints.

C.9 Paronychia

Paronychia is an inflammatory disorder of the nail folds. It is generally classified as acute and chronic. Acute cases are caused by trauma to the nail folds or cuticle.

C.9.a Medications

For most patients, ibuprofen, naproxen, or other older generation nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence suggests acetaminophen is modestly less effective. There is evidence that
NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.

C.9.a.i NSAIDs for Treatment of Paronychia Pain

**Recommended** - for treatment of paronychia pain.

*Indications*: For paronychia pain, NSAIDs are recommended for treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

*Frequency/Duration*: As needed use may be reasonable for many patients.

*Indications for Discontinuation*: Resolution of foot/ankle pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.

C.9.a.ii NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding

**Recommended** – concomitant use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine Type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

*Indications*: For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.

*Frequency/Dose/Duration*: Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding.

*Indications for Discontinuation*: Intolerance, development of adverse effects, or discontinuation of NSAID.

C.9.a.iii NSAIDs for Patients at Risk for Cardiovascular Adverse Effects

Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.

**Recommended** - Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse.

**Recommended** - If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to minimize the potential for the NSAID to counteract the beneficial effects
of aspirin, the NSAID should be taken at least 30 minutes after or eight hours before the daily aspirin.

C.9.a.iv Acetaminophen for Treatment of Paronychia Pain

**Recommended** - for treatment of paronychia pain, particularly in patients with contraindications for NSAIDs.

*Indications:* All patients with foot/ankle pain, including acute, subacute, chronic, and postoperative.

*Dose/Frequency:* Per manufacturer’s recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

*Indications for Discontinuation:* Resolution of pain, adverse effects or intolerance.

C.9.a.v Topical Antibiotics for the Treatment of Acute Paronychia

**Recommended** – for treatment of acute paronychia.

C.9.a.vi Systemic Antibiotics for the Treatment of Complications of Paronychia

**Recommended** – for the treatment of complications of paronychia such as signs of systemic infection or surrounding cellulitis.

C.9.a.vii Topical and Systemic Antifungals for the Treatment of Select Patients with Chronic Paronychia Due to Fungal Infections

**Recommended** – for the treatment of chronic paronychia

C.9.a.viii Topical Glucocorticosteroid Cream for Treatment of Select Patients with Chronic Paronychia Not Due to Bacterial or Fungal Infections

**Recommended** – for treatment of select patients with chronic paronychia with chronic paronychia not due to bacterial or fungal infections.

C.9.a.ix Topical and Systemic Antibiotics for Treatment of Secondary Chronic Paronychia Due to Bacterial Infections

**Recommended** – for treatment of secondary chronic paronychia infections.

C.9.b Treatment

C.9.b.i Cryotherapy / Heat

*Warm Compresses to Treat Acute Phase of Paronychia.*

**Recommended** – for treatment of acute paronychia.
C.9.b.ii  Surgery

C.9.b.ii.a  En Bloc Excision of the Proximal Nail Fold and Eponychial Marsupialization, With or Without Nail Plate Removal

**Recommended** – for treatment of recurrent paronychias.

**Recommended** – surgical intervention, including en bloc excision of the proximal nail fold and eponychial marsupialization, with or without nail plate removal for treatment of chronic paronychia.

C.9.b.iii  Other

C.9.b.iii.a  Incision and Drainage of Abscess Formed in Response to Acute Paronychia

**Recommended** – in response to acute paronychia.

C.10  Foot Drop

Foot drop is a weakness in the dorsiflexion strength of the affected lower extremity resulting in an abnormal gait pattern. Foot drop is most commonly caused by a variety of central and peripheral nervous system disorders, although any disorder affecting muscle strength may cause foot drop. Foot drop results in an abnormal gait pattern most often because the ankle of the weak side cannot undergo voluntary dorsiflexion.

The acute onset of foot drop after ipsilateral leg trauma may be a manifestation of compartment syndrome. Acute cases of foot drop are urgencies if not emergencies due to the potential for significant enduring impairments.

Acute trauma followed by foot drop and lower leg pain may mark compartment syndrome, which is one of the surgical emergent causes of foot drop.

C.10.a  Diagnostic Studies

Diagnostic studies to determine the cause of foot drop most often include MRI of the brain, spinal cord and/or MRI of the periphery and electrodiagnostic studies of the peripheral nerves as clinically indicated.

C.10.a.i  Diagnostic Studies for Diagnosis of Foot Drop

**Recommended** – to determine cause of foot drop (see General Principles A.12 – Diagnostic Imaging and Testing Procedures).
C.10.b Treatments

C.10.b.i Rehabilitation Therapy

Rehabilitation (supervised formal therapy) required as a result of a work-related injury should be focused on restoring functional ability required to meet the patient’s daily and work activities and return to work; striving to restore the injured worker to pre-injury status in so far as is feasible.

Active therapy requires an internal effort by the patient to complete a specific exercise or task. Passive therapy are those interventions not requiring the exertion of effort on the part of the patient, but rather are dependent on modalities delivered by a therapist. Generally passive interventions are viewed as a means to facilitate progress in an active therapy program with concomitant attainment of objective functional gains. Active interventions should be emphasized over passive interventions.

The patient should be instructed to continue both active and passive therapies at home as an extension of the treatment process in order to maintain improvement levels.

Assistive devices may be included as an adjunctive measure incorporated into the rehabilitation plan to facilitate functional gains.

C.10.b.i.a Taping for Treatment of Foot Drop

Not Recommended - for the treatment of foot drop.

Rationale for Recommendation: Generally, braces are used for foot drop.

Evidence for the Use of Taping

C.10.b.ii Other

C.10.b.ii.a Ankle-foot Orthotics for Treatment of Foot Drop

Recommended - for the treatment of foot drop.

Evidence for use of Orthotics

C.11 Tarsal Tunnel Syndrome (TTS)

Tarsal Tunnel Syndrome (TTS) is a relatively infrequent condition defined as an entrapment neuropathy of the tibial nerve or one of its branches from its entry point under the flexor retinaculum below the medial malleolus to the end of its lateral and medial plantar and posterior calcaneal branches, which innervate the base of the foot. TTS is
described by the constellation of symptoms of intermittent tingling, numbness or burning paresthesias in the toes and the plantar surface of the foot.

In the absence of neuropathic findings (sensory or motor involvement) four to six weeks of conservative care before using invasive measures may be reasonable. The commonly prescribed conservative measures are intended to relieve pressure and pain. These include cold, taping, exercises (especially posterior tibial nerve stretching), anti-inflammatory medications, splints, orthotic devices and supportive footwear.

There are no well-established standard diagnostic criteria for TTS. Clinicians should maintain a high level of suspicion for TTS in patients presenting with pain and paresthesias of the plantar foot that worsen with prolonged standing and walking, or cause interruption of sleep.

**C.11.a Diagnostic Studies**

**C.11.a.i Nerve Conduction Studies (NCS) for Diagnosis and Pre-operative Assessment of TTS Patients**

*Recommended* - for confirming the diagnosis of entrapment of the tibial nerve at the ankle for cases that do not improve with conservative treatment or if considering surgical release after excluding the possibility of other causes such as polyneuropathy and radiculopathy.

**C.11.a.ii NCS for Initial Evaluation of TTS Patients**

*Not Recommended* - for the initial evaluation and most TTS patients as NCS does not change the management of the condition during the first four to six weeks while conservative therapy is being tried.

**C.11.a.iii Electromyography (EMG) for Initial Evaluation, Diagnosis or Pre-operative Assessment of TTS Patients**

*Not Recommended* - for initial evaluation, diagnosis or pre-operative assessment of TTS patients. Electromyography (as distinguished from a nerve conduction study) is not generally recommended as there is no quality evidence demonstrating the utility of EMG in the diagnosis of TTS.

*Rationale for Recommendations*: NCS is recommended for diagnosis of entrapment of the tibial nerve at the ankle and for pre-operative assessment, but is not recommended for initial evaluation and most TTS patients.

**C.11.a.iv MRI for Diagnosis of TTS**

*Recommended* - for the diagnosis of select cases of clinically suspected TTS that has failed conservative management or if a mass lesion is suspected.

**C.11.a.v MRI to Diagnose TTS**

*Not Recommended* - for the initial evaluation of TTS.
C.11.a.vi Use of Ultrasound as an Aid to NCS

**Recommended** - as an aid to NCS as it may be beneficial to identify suspected space occupying lesions in the tarsal tunnel after failed conservative management, or as an adjunct to guide interventional therapies.

C.11.a.vii Routine Use of Diagnostic Ultrasound

**Not Recommended** - as a routine diagnostic test for TTS.

*Rational for Recommendations*: The routine use of ultrasound for initial evaluation is not recommended. Ultrasound studies should be reserved for patients that have failed conservative therapy. Use as an adjunct to guide interventional therapies may be useful.

C.11.b Medications

For most patients, ibuprofen, naproxen, or other older generation nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence suggests acetaminophen is modestly less effective. There is evidence that NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.

C.11.b.i Non-Steroidal Anti-inflammatory Drugs (NSAIDs) and Acetaminophen for TTS Pain

**Recommended** - for treatment of TTS

*Indications*: For TTS Pain, NSAIDs are recommended for treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

*Frequency/Duration*: As needed use may be reasonable for many patients.

*Indications for Discontinuation*: Resolution of foot/ankle pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.

C.11.b.ii NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding

**Recommended** – concomitant use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine Type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

*Indications*: For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk
patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.

Frequency/Dose/Duration: Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding.

Indications for Discontinuation: Intolerance, development of adverse effects, or discontinuation of NSAID.

C.11.b.iii NSAIDs for Patients at Risk for Cardiovascular Adverse Effects
Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.

Recommended: Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse.

Recommended: If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to minimize the potential for the NSAID to counteract the beneficial effects of aspirin, the NSAID should be taken at least 30 minutes after or 8 hours before the daily aspirin.

C.11.b.iv Acetaminophen for Treatment of TTS Pain

Recommended - for treatment of TTS Pain, particularly in patients with contraindications for NSAIDs.

Indications: All patients TTS pain. Acetaminophen may provide enough mild analgesic relief to allow the patient to exercise or function at a higher level.

Dose/Frequency: Per manufacturer’s recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

Indications for Discontinuation: Resolution of pain, adverse effects or intolerance.

C.11.b.v Oral Systemic Glucocorticosteroids for Treatment of TTS

Recommended - for treatment of TTS patients who decline tarsal tunnel injection.

Indications – Tarsal tunnel syndrome unresponsive to splinting. Most patients should be injected rather than given oral steroids. However, among those declining injection, oral glucocorticosteroids may be warranted.
Frequency/Dose: It is recommended that one course (10 to 14 days) of oral glucocorticosteroid be prescribed, rather than repeated courses. Prescriptions of low rather than high doses are recommended to minimize potential for adverse effects.

Opioids
Opioids have occasionally been used to treat patients with TTS. These medications have primarily been used for a few nights in the post-surgical period (see Non Acute Pain Guideline).

C.11.b.vi Routine Use of Opioids for Treatment of Pain from TTS

**Not Recommended** - for treatment of patients with pain from TTS.

**Rationale for Recommendations:** The vast majority of patients with TTS do not have pain of sufficient intensity to require opioids. Patients having such degrees of pain should generally have investigations performed for alternative diagnoses. They are not recommended for routine use. Opioids are recommended for brief, select use in postoperative patients with primary use at night to achieve sleep postoperatively.

C.11.b.vii Opioids for Pain Treatment of TTS in Select Patients Post Op

**Recommended** - limited use (not more than seven days) for select patients

**Indications:** Patients who have undergone recent tarsal tunnel release and have large incisions or encountered significant complications and whose pain cannot be managed with other means.

**Evidence for the Use of Opioids for TTS**

C.11.b.viii Diuretics for Routine Treatment of TTS

**Not Recommended** - for routine treatment of TTS.

**Rationale for Recommendation:** Most of the medical conditions described as risk factors for TTS do not involve edema or swelling of the lower extremities.

C.11.b.ix Vitamins, Including Pyridoxine

**Not Recommended** - for the treatment of TTS in patients without vitamin deficiencies.

C.11.b.x Lidocaine Patches for Treatment of TTS

**Recommended** - for treatment of select cases of TTS.

**Indications:** Patients with moderate to severe TTS with pain as a central complaint and in whom other treatable causes of the pain have been
eliminated. Generally should have previously been treated with likely more efficacious treatment strategies.

*Frequency/Duration:* Per manufacturer’s recommendation.

*Indications for Discontinuation:* Resolution, intolerance, adverse effects, lack of benefits, or failure to progress over a trial of at least a couple weeks.

**C.11.c Treatments**

**C.11.c.i Cyrotherapy / Heat**

**C.11.c.i.a Self-application of Ice or Heat for Treatment of TTS**

*Recommended* - for the treatment of TTS.

*Rationale for Recommendations:* Ice and heat may help particularly with more acute symptoms.

**C.11.c.ii Mobilization / Immobilization**

**C.11.c.ii.a Nocturnal Splints for Treatment of TTS**

*Not Recommended* - nocturnal splinting for treatment of TTS.

**C.11.c.iii Rehabilitation**

**Therapy**

Rehabilitation (supervised formal therapy) required as a result of a work-related injury should be focused on restoring functional ability required to meet the patient’s daily and work activities and return to work; striving to restore the injured worker to pre-injury status in so far as is feasible.

Active therapy requires an internal effort by the patient to complete a specific exercise or task. Passive therapy are those interventions not requiring the exertion of effort on the part of the patient, but rather are dependent on modalities delivered by a therapist. Generally passive interventions are viewed as a means to facilitate progress in an active therapy program with concomitant attainment of objective functional gains. Active interventions should be emphasized over passive interventions.

The patient should be instructed to continue both active and passive therapies at home as an extension of the treatment process in order to maintain improvement levels.
Assistive devices may be included as an adjunctive measure incorporated into the rehabilitation plan to facilitate functional gains.

**C.11.c.iii.a Rest for Treatment of More Symptomatic Cases of TTS**

- **Recommended** - for the treatment of TTS.

_Rationale for Recommendations:_ Ankle rest may be beneficial for the more symptomatic cases where aggravating factors include constant standing or walking.

**C.11.c.iii.b Exercise**

- **Recommended** - for the treatment of TTS.

_Rationale for Recommendation:_ Exercise regimens for tendon gliding or nerve gliding may be appropriate with documentation of improved function and decreased pain.

**C.11.c.iii.c Taping**

- **Not Recommended** - for the treatment of TTS.

**C.11.c.iii.d Magnets**

- **Not Recommended** - for the treatment of TTS.

**C.11.c.iii.e Acupuncture**

- **Not Recommended** - for the treatment of TTS.

_Rationale for Recommendation:_ There are other interventions with documented efficacy. Therefore, the use of acupuncture for treatment of TTS is not recommended.

**C.11.c.iii.f Manipulation and Mobilization of the Distal Lower Extremity**

- **Not Recommended** - for the treatment of TTS.

**C.11.c.iii.g Ultrasound**

- **Not Recommended** - for the treatment of TTS

**C.11.c.iii.h Iontophoresis**

- **Not Recommended** - for the treatment of TTS.

_Rationale for Recommendation:_ Other treatments have documented efficacy and should be used preferentially.
C.11.c.iii.i Phonophoresis

**Not Recommended** - for the treatment of TTS.

*Rationale for Recommendation:* Other treatments have documented efficacy and should be used preferentially.

*Evidence for the Use of Phonophoresis*

C.11.c.iv Injection Therapy

C.11.c.iv.a Glucocorticosteroid Injections

**Recommended** - as part of a conservative management strategy for treatment of TTS.

*Rationale for Recommendation:* Injections are commonly reported as part of conservative therapy and as an additional mode for confirmation of suspected diagnosis of TSS. Thus, if a more conservative treatment strategy fails to improve the condition, glucocorticosteroid injections may be useful.

C.11.c.iv.b Insulin Injections

**Not Recommended** - for the treatment of TTS.

C.11.c.iv.c Botulinum Injections

**Not Recommended** - for the treatment of TTS

C.11.c.v Surgery

C.11.c.v.a Surgical Release for Space Occupying Lesion

**Recommended** - Surgical release of posterior tibial nerve impingement at the tarsal tunnel upon failure of conservative treatment and in the presence of space occupying lesion. Surgical release for cases with nonspecific causes are otherwise expected to have mixed results and patients should be counseled regarding potential lack of benefit before consideration of surgery.

C.11.c.vi Other

C.11.c.vi.a Orthotics for Treatment of Select Patients with TTS

**Recommended** - selectively for those with TTS thought to be of biomechanical origin.
C.12 Ankle Sprain

Injuries to the ankle are common and are a frequent reason for seeking acute care.

Ankle sprain injuries involve tear of one or more ligaments in any of the three ligament groups. The majority of ankle sprains involve only the lateral ligaments, with approximately 15% involving the medial ankle. The natural course of the lateral ankle sprain is rapid improvement. Ten to 20% of patients with acute ankle sprain may develop chronic ankle instability.

Classification systems for lateral ankle sprain severity are based on physical examination findings and are used to define the extent of ligament injury.

Sprain: Injury, not necessarily permanent, of a ligament.
   S, Grade I: overstretching or slight tearing without instability.
   S, Grade II: incomplete tearing.
   S, Grade III: complete tear or rupture.

Red flags, including fracture, should be considered.

C.12.a Diagnostic Studies

C.12.a.i Routine Use of Arthrography in Diagnosis of Acute, Subacute or Chronic Ankle Sprain

**Not Recommended** - for evaluation of acute, subacute or chronic ankle sprain.

*Rationale for Recommendations*: Arthrography is invasive, is associated with adverse effects including risks from dye and post-procedure pain. MRI, CT, and ultrasound have essentially replaced plain arthrography in current practice.

C.12.a.ii X-Ray in Assessment of Acute Ankle Sprain When Fracture is Not Suspected

**Not Recommended** - for evaluation of acute ankle sprain when fracture is not suspected.

C.12.a.iii X-Ray in Assessment of Acute Ankle Sprain When Fracture is Suspected

**Recommended** - if fracture is likely and the differential diagnosis reflects suspicion of fracture.

*Rationale for Recommendations*: The primary purpose of obtaining radiologic imaging for the acute ankle injury is to evaluate for the presence of ankle or foot fractures. Ankle fracture occurs in approximately 15% of patients with ankle sprain.

*Indications*: Suspicion of fracture or if the history or physical is clinically suspicious for an injury other than an ankle sprain.
Views: Anteroposterior, lateral, and mortise radiographs should be obtained.

C.12.a.iv Routine Stress X-Ray for Evaluation of Ligament Rupture in Acute Ankle Sprain

*Not Recommended* - for evaluation of acute ankle ligament rupture.

C.12.a.v Routine Stress X-Ray for Evaluation of Ligament Rupture in Subacute or Chronic Ankle Sprain

*Not Recommended* - for evaluation of subacute or chronic ankle pain.

*Rationale for Recommendations*: Plain films are not required for the diagnosis of acute ankle sprain as x-ray is poor at diagnosing soft-tissue disorders. The use of plain film x-ray rather is utilized for evaluation of accompanying ankle or foot fracture, orientation of fracture plane(s), and magnitude of the involvement of the articular surfaces, which if present may alter management in favor of surgery. X-ray is indicated based on high clinical suspicion. Therefore, x-ray is recommended for assessment of suspected ankle or foot fracture.

*Evidence for the Use of X-ray for Evaluation of Ankle Fractures*

C.12.a.vi CT for Assessment of Subacute or Chronic Ankle Sprain

*Recommended* - for the assessment of select patients with subacute or chronic ankle sprain.

*Indications* – Patients who have no improvement with non-operative therapy after four to six weeks, persistent pain with weight bearing, or chronic feeling of instability; ankle injuries that involve crepitus, catching or locking, as these symptoms may be associated with a displaced osteochondral fragment.

C.12.a.vii CT for Assessment of Acute Ankle Sprain

*Not Recommended* - for assessment of patients with acute ankle sprain.

C.12.a.viii Magnetic Resonance Arthrography (MRA) for Assessment of Subacute or Chronic Ankle Sprain

*Not Recommended* - for the assessment of subacute or chronic ankle sprain.

C.12.a.ix MRA for Assessment of Acute Ankle Sprain

*Not Recommended* - for the assessment of acute ankle sprain.
C.12.a.x  Magnetic Resonance Imaging (MRI) for Assessment of Subacute or Chronic Ankle Sprain

**Recommended** - for the assessment of select patients with subacute or chronic ankle sprain.

*Indications:* Patients who have no improvement with non-operative therapy after four to six weeks, persistent pain with weight bearing, or chronic feeling of instability; ankle injuries that involve crepitus, catching or locking, as these symptoms may be associated with a displaced osteochondral fragment.

*Rationale For Recommendation:* MRI is used to evaluate ligament, osteochondral injury such as talar dome lesions, fractures, ankle impingement, and other soft-tissue injuries.

C.12.a.xi  MRI for Assessment of Acute Ankle Sprain

**Not Recommended** - for the assessment of acute ankle sprain.

C.12.a.xii Bone Scans for Assessment of Acute Ankle Sprain

**Recommended** - for select patients with acute ankle sprain.

*Indications:* Suspected stress fracture, infection, or tumor.

C.12.a.xiii Bone Scans for Assessment of Subacute or Chronic Ankle Sprain

**Not Recommended** - for patients with subacute or chronic ankle sprain.

C.12.a.xiv Ultrasound for Diagnosis of Subacute or Chronic Ankle Sprain

**Not Recommended** - for evaluation of patients with subacute or chronic ankle sprain.

C.12.a.xv Electrodiagnostic Studies of the Peroneal Nerve

**Recommended** – for select patients with recurrent / recalcitrant lateral sprains.

*Indications* – To rule out peroneal neuropath in Patients with Lateral sprains as a result of marked inversion injury.

C.12.b  Medications

For most patients, ibuprofen, naproxen, or other older generation nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence suggests acetaminophen is modestly less effective. There is evidence that NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.
C.12.b.i  Acetaminophen for Treatment of Acute, Subacute, or Chronic Sprain Injury Pain

**Recommended** - for treatment of acute, subacute or chronic ankle sprain injury pain, particularly in patients with contraindications for non-steroidal anti-inflammatory (NSAIDs).

*Indications:* All patients with foot/ankle pain, including acute, subacute, chronic, and postoperative.

*Dose/Frequency:* Per manufacturer’s recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

*Indications for Discontinuation:* Resolution of pain, adverse effects or intolerance.

C.12.b.ii  Non-Steroidal Anti-inflammatory Drugs (NSAIDs)

NSAIDs for Treatment of Acute, Subacute, Chronic Ankle Sprain

**Recommended** - for treatment of acute, subacute, chronic, or postoperative Ankle Sprain.

*Indications:* For ankle sprain pain, NSAIDs are recommended for treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

*Frequency/Duration:* As needed use may be reasonable for many patients.

*Indications for Discontinuation:* Resolution of foot/ankle pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.

C.12.b.iii  NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding

**Recommended** – concominent use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine Type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

*Indications:* For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.

*Frequency/Dose/Duration:* Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding.
Indications for Discontinuation: Intolerance, development of adverse effects, or discontinuation of NSAID.

C.12.b.iv NSAIDs for Patients at Risk for Cardiovascular Adverse Effects

Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.

Recommended - Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse.

Recommended - If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to minimize the potential for the NSAID to counteract the beneficial effects of aspirin, the NSAID should be taken at least 30 minutes after or eight hours before the daily aspirin.

Evidence for the Use of Acetaminophen for Ankle Sprain

Evidence for the Use of NSAIDs for Ankle Sprain

C.12.b.v Opioids for Select Acute or Postoperative Ankle Sprain

Recommended - for no more than one week for select patients with severe pain related to acute ankle sprain. Limited use of opioids for no more than one week may be indicated for those that have undergone ankle ligament repair surgery or those who encountered surgical complications.

Indication: Highly selective use. Severe pain with acute ankle sprain and postoperative pain management. Generally to be used only with either demonstrated insufficient control of pain with NSAID or severe sprain/postoperative pain.

Frequency/Dose/Duration: Frequency and dose per manufacturer’s recommendations; may be taken scheduled or as needed; generally suggested to be taken for short courses of a few days.

Indications for Discontinuation: Sufficient pain management with other methods such as NSAIDs, resolution of pain, intolerance, adverse effects, lack of benefits, or failure to progress over a couple weeks.

Rationale for Recommendation: The vast majority of patients with ankle sprain generally do not have pain sufficient to require opioids.

Some patients have insufficient pain relief with NSAIDs, thus judicious use of opioids may be helpful, particularly for nocturnal use. Opioids are recommended for brief select use in postoperative patients primarily at night to achieve postoperative sleep.

Evidence for the Use of Opioids for Ankle Sprain
C.12.b.vi Lidocaine Patches for Acute, Subacute, or Chronic Ankle Sprain

**Not Recommended** - for the treatment of acute, subacute, or chronic ankle sprain.

**Evidence for the Use of Lidocaine Patches for Ankle Sprain**

C.12.b.vii Topical NSAIDs for Acute Ankle Sprain

**Recommended** - for the treatment of acute ankle sprain.

**Indications**: Acute ankle sprain or patients with contraindications for oral treatment or who prefer not to take oral medications. No evidence of comparative superiority of one topical NSAID over another.

**Frequency/Duration**: Frequency per manufacturer’s recommendation. Topical NSAID use has been reported for one to three weeks.

**Indications for Discontinuation**: Resolution, intolerance, adverse effects, or lack of benefits.

**Rationale for Recommendation**: Topical NSAIDs are used to deliver medication locally and superficially in musculoskeletal disorders, including ankle sprain disorders.

C.12.b.viii Topical NSAIDs for Subacute or Chronic Ankle Sprain

**Not Recommended** - for the treatment of subacute, or chronic ankle sprain.

**Evidence for the Use of Topical NSAIDs for Ankle Sprain**

C.12.c Treatments

C.12.c.i Rest, Ice, Compression, Elevation (RICE)

C.12.c.i.a Immediate Non-weight Bearing (Rest) for Acute Ankle Sprain

**Recommended** - as an initial intervention for acute ankle sprain for patients unable to tolerate weight.

**Indications**: Acute mild, moderate, and severe ankle sprain patients who are unable to tolerate weight bearing. A short period of up to 48 hours may be prescribed based on tolerance and ability to bear weight. Early mobilization is recommended.

**Frequency/Duration**: Up to 48 hours of non-weight bearing; early mobilization, progressive weight bearing as tolerated, addition of home therapeutic exercises.
Indications for Discontinuation: Resolution, ability to tolerate weight.

Evidence for the Use of RICE for Ankle Sprain

C.12.c.i.b Cryotherapy for Acute Ankle Sprain

Recommended - for treatment of acute ankle sprains.

Indications: Acute ankle sprain.

Frequency/Duration: Self-application for 10 to 20 minutes every two hours for up to three days as needed.

Indications for Discontinuation: Resolution, adverse effects, noncompliance.

Evidence for the Use of Ice/Cryotherapy for Ankle Sprain

C.12.c.ii Cryotherapy / Heat

C.12.c.ii.a Heat for Acute Ankle Sprain

Not Recommended - for the treatment of acute ankle sprain.

Evidence for the Use of Heat for Ankle Sprain

C.12.c.iii Immobilization

C.12.c.iii.a Ankle Brace (Orthosis) for Acute Ankle Sprain

Recommended - for treatment of acute ankle sprain with optional use as needed by the patient for mild and moderate sprains.

Evidence for the Use of Ankle Brace Support (Pneumatic/Gel) for Ankle Sprain
Evidence for the Use of Ankle Support or Brace for Ankle Sprain

C.12.c.iii.b Walking Boot for Acute Ankle Sprain

Not Recommended - of acute ankle sprains.

C.12.c.iii.c Walking Boot for Select Cases of Severe Ankle Sprain

Recommended - for select cases of severe ankle sprains.

Evidence for the Use of Walking Boots for Ankle Sprain

C.12.c.iii.d Early Mobilization for Acute Ankle Sprain
**Recommended** - for acute ankle sprains without fracture.

*Indications:* Acute ankle sprains (severe sprains should undergo no more than three weeks of immobilization, splints should be sufficient for immobilization; ankle sprains that are mild or moderate should not undergo immobilization.

*Rationale for Recommendations:* Early mobilization is recommended over immobilization for most patients

**C.12.c.iii.e Immobilization for Acute Mild to Moderate Ankle Sprain**

**Not Recommended** - for patients with acute mild to moderate ankle sprain as splints should be sufficient.

*Rationale for Recommendation:* Mild acute sprains are generally self-limited and respond well to early mobilization and other therapies; therefore, casting is not recommended.

**C.12.c.iii.f Immobilization for Severe Ankle Sprain**

**Recommended** – splinting for immobilization for severe ankle sprain.

*Indications:* Severe ankle sprain.

*Frequency/Duration:* Application of a splint for ten days to three weeks after a 48 hour period of elevation and non-weight bearing.

*Rationale for Recommendation:* Casting is restrictive of activity, including return to work, impairs driving performance more than bracing, and is associated with risk for deep venous thrombosis. Cast immobilization is therefore not recommended. Splinting is recommended for immobilization of severe ankle sprain.

**Evidence for the Use of Early Mobilization for Ankle Sprain**

**C.12.c.iv Rehabilitation**

Rehabilitation (supervised formal therapy) required as a result of a work-related injury should be focused on restoring functional ability required to meet the patient’s daily and work activities and return to work; striving to restore the injured worker to pre-injury status in so far as is feasible.

Active therapy requires an internal effort by the patient to complete a specific exercise or task. Passive therapy are those interventions not requiring the exertion of effort on the part of the patient, but rather are dependent on modalities delivered by a therapist. Generally passive interventions are viewed as a means to facilitate progress in an active therapy program with concomitant attainment of objective functional
gains. Active interventions should be emphasized over passive interventions.

The patient should be instructed to continue both active and passive therapies at home as an extension of the treatment process in order to maintain improvement levels.

Assistive devices may be included as an adjunctive measure incorporated into the rehabilitation plan to facilitate functional gains.

C.12.c.iv.a Therapy – Active

Therapeutic Exercise

**Recommended** – for select patients with acute, subacute or chronic ankle sprain

**Frequency/Dose/Duration** – Total numbers of visits may be as few as two to three for patients with mild functional deficits or up to 12 to 15 with more severe deficits with documentation of ongoing objective functional improvement.

When there are ongoing functional deficits, more than 12 to 15 visits may be indicated if there is documentation of functional improvement towards specific objective functional goals (e.g., range of motion, advancing ability to perform work activities). As part of the rehabilitation plan a home exercise program should be developed and performed in conjunction with the therapy.

C.12.c.iv.b Therapy - Passive

Rest, Ice, Compression, Elevation (RICE)

C.12.c.iv.b.i Immediate Non-weight Bearing (Rest) for Acute Ankle Sprain

**Recommended** - as an initial intervention for acute ankle sprain for patients unable to tolerate weight.

**Indications**: Acute mild, moderate, and severe ankle sprain patients who are unable to tolerate weight bearing. A short period of up to 48 hours may be prescribed based on tolerance and ability to bear weight. Early mobilization is recommended.

**Frequency/Duration**: Up to 48 hours of non-weight bearing; early mobilization, progressive weight bearing as tolerated, addition of home therapeutic exercises.
Indications for Discontinuation: Resolution, ability to tolerate weight.

Evidence for the Use of RICE for Ankle Sprain

C.12.c.iv.b.ii Cryotherapy for Acute Ankle Sprain

Recommended - for treatment of acute ankle sprains.

Indications: Acute ankle sprain.

Frequency/Duration: Self-application for 10 to 20 minutes every two hours for up to three days as needed.

Indications for Discontinuation: Resolution, adverse effects, noncompliance.

Evidence for the Use of Ice/Cryotherapy for Ankle Sprain

C.12.c.v Cryotherapy / Heat

C.12.c.v.a Heat for Acute Ankle Sprain

Not Recommended - for the treatment of acute ankle sprain.

Evidence for the Use of Heat for Ankle Sprain

C.12.c.v.b Compression Therapy for Acute Ankle Sprain

Not Recommended - for acute ankle sprains.

C.12.c.v.c Tubigrip for Acute Ankle Sprain

Not Recommended - for acute ankle sprains.

C.12.c.v.d Tape, Elastic Wrap or Tubular Elastic for Acute Ankle Sprain

Not Recommended - for acute ankle sprains.

Evidence for the Use of Compression Bandage, Wrap, or Tape for Ankle Sprain

C.12.c.v.e Intermittent Elevation for Acute Ankle Sprain

Recommended - for controlling edema of acute ankle sprains.
Indications: Acute ankle sprain that manifest significant edema.

Indications for Discontinuation: Resolution, adverse effects, noncompliance.

Evidence for the Use of Elevation for Ankle Sprain

C.12.c.v.f Contrast Bath Therapy for Acute Ankle Sprain

Not Recommended - for the treatment of acute ankle sprain.

Evidence for the Use of Contrast Bath for Ankle Sprain

C.12.c.v.g High-Voltage Pulsed Current for Acute Ankle Sprain

Not Recommended - for acute ankle sprains.

C.12.c.v.h Magnets for Acute, Subacute, or Chronic Ankle Sprain

Not Recommended - for treatment of acute, subacute, or chronic ankle sprain.

Evidence for the Use of Magnets for Ankle Sprain

C.12.c.v.i Diathermy for Acute, Subacute, or Chronic Ankle Sprain

Not Recommended - for the treatment of acute, subacute, or chronic ankle sprain.

Evidence for the Use of Diathermy for Ankle Sprain

C.12.c.v.j Low Frequency Electrical Stimulation for Acute, Subacute, or Chronic Ankle Sprain

Not Recommended - for acute, subacute, or chronic ankle sprain.

C.12.c.v.k High-voltage Pulsed Electrical Stimulation for Acute, Subacute, or Chronic Ankle Sprain

Not Recommended - as a treatment for acute, subacute, or chronic ankle sprain.

Evidence for the Use of Electrical Stimulation for Ankle Sprain

C.12.c.v.l Iontophoresis for Acute, Subacute, or Chronic Ankle Sprain
Not Recommended - for treatment of acute, subacute, or chronic ankle sprain.

Evidence for the Use of Iontophoresis for Ankle Sprain

C.12.c.v.m Low-level Laser Therapy for Acute, Subacute, or Chronic Ankle Sprain

Not Recommended - for treatment of acute, subacute, or chronic ankle sprain.

Evidence for the Use of Low-level Laser Therapy for Ankle Sprain

C.12.c.v.n Phonophoresis for Acute, Subacute, or Chronic Ankle Sprain

Not Recommended - for treatment of acute, subacute, or chronic ankle sprain.

Evidence for the Use of Phonophoresis for Ankle Sprain

C.12.c.v.o Therapeutic Ultrasound for Acute, Subacute, or Chronic Ankle Sprain

Not Recommended - for the treatment of acute, subacute, or chronic ankle sprain.

Evidence for the Use of Therapeutic Ultrasound for Ankle Sprain

C.12.c.v.p Acupuncture for Acute, Subacute, or Chronic Ankle Sprain

Not Recommended - for treatment of acute, subacute, or chronic ankle sprain.

Evidence for the Use of Acupuncture for Ankle Sprain

C.12.c.v.q Hyperbaric Oxygen Therapy for Acute, Subacute, or Chronic Ankle Sprain

Not Recommended - for treatment of acute, subacute, or chronic ankle sprain.

Evidence for the Use of Hyperbaric Oxygen for Ankle Sprain

C.12.c.v.r Manipulation or Mobilization for Acute or Subacute Ankle Sprain

Not Recommended - for the treatment of acute or subacute ankle sprain.
C.12.c.v.s  Manipulation or Mobilization for Chronic Recurrent Ankle

**Not Recommended** - for the treatment of chronic recurrent ankle sprain.

*Evidence for the Use of Manipulation and Mobilization for Ankle Sprain*

---

C.12.c.v.i Injection Therapy

C.12.c.v.i.a  Autologous Blood Injection for Acute, Subacute, or Chronic Ankle Sprain

**Not Recommended** - as a treatment for acute, subacute, or chronic ankle sprain.

*Evidence for the Use of Autologous Blood Injections for Ankle Sprain*

C.12.c.v.i.b  Glucocorticosteroid Injections for Acute, Subacute, or Chronic Ankle Sprain

**Not Recommended** - for treatment of acute, subacute, or chronic ankle sprain.

*Evidence for the Use of Injected Glucocorticosteroids for Ankle Sprain*

C.12.c.v.i.c  Hyaluronic Acid Injections for Acute, Subacute, or Chronic Ankle Sprain

**Not Recommended** - for the treatment of acute, subacute, or chronic ankle sprains.

*Evidence for the Use of Hyaluronic Acid for Ankle Sprain*

C.12.c.v.i.d  Prolotherapy Injections for Acute, Subacute, Chronic or Ankle Sprains

**Not Recommended** - for the treatment of most acute, subacute or chronic and postoperative ankle sprains.

*Evidence for the Use of Polidocanol Injections*

C.12.c.v.i.e  Platelet Rich Plasma Injections for Acute, Subacute, or Chronic Ankle Sprain

**Not Recommended** - for the treatment of acute, subacute, or chronic ankle sprains.
Evidence for the Use of Platelet Rich Plasma for Ankle Sprain

C.12.c.vii Surgery

C.12.c.vii.a Surgery for Treatment of Acute or Subacute Ankle Ligament Tear

Not Recommended - for routine lateral ligament tear associated with acute or subacute ankle sprain.

C.12.c.vii.b Surgery for Treatment of Chronic Ankle Instability (CAI)

Recommended - for select cases of chronic ankle instability.

Indications: Chronic ankle instability of at least three months duration, lateral ankle ligament laxity, and failure of non-operative therapies including therapy and use of ankle orthosis.

Rationale for Recommendations: Persistent functional instability of a chronic nature may be considered for ligament reconstruction.

Evidence for the Use of Surgical Intervention for Chronic Ankle Instability

Evidence for the Use of Acute Surgical Repair for Ankle Ligament Tear

C.12.c.vii.c Postoperative Management of Ankle Instability

Recommended - Short-term cast immobilization with early mobilization and therapy for ankle instability.

Rationale for Recommendation: Immobilization or early motion and therapy are described as frequent postoperative management techniques.

Evidence for the Use of Postoperative Management for Ankle Instability

C.13 Mid-Tarsus Pain and Sprains

Mid-tarsus or mid-foot pain and sprains frequently involve the ligaments of the mid-foot. A primary diagnostic focus is to eliminate the diagnosis of midfoot fracture. Metatarsalgia is included in this category as is metatarsophalangeal joint sprain. However, metatarsalgia is a broad categorization of forefoot pain that also includes numerous other conditions (e.g., Morton’s neuroma).
C.13.a Diagnostic Studies

C.13.a.i Weight Bearing X-Rays

Recommended – AP and lateral views without obliques; often bilateral for comparative purposes:
- Often normal in mild injuries (Grade 1 Sprains).
- Generally abnormal in moderate (Grade 2 Sprains).
- Always abnormal in severe injuries (Grade 3 Sprains).

C.13.a.ii CT Scans

Recommended – in uncertain cases and in select pre-operative cases.

C.13.b Treatments

C.13.b.i Mobilization / Immobilization

C.13.b.i.a In mobilization in a Short-Leg Walking Boot or Cast

Recommended – for mild to moderate cases without diastasis.

Duration of Therapy – four to six weeks with repeat x-rays and evaluation for stability at two weeks.

C.13.b.ii Surgery

C.13.b.ii.a Surgery

Recommended – for all severe cases, unstable injuries, and those with significant diastasis (e.g. >2mm).

C.14 Foot Neuroma (Morton’s Neuroma)

Morton’s Neuroma is a common neuralgia affecting the web spaces of the toes, typically the third toe. The pain of Morton’s Neuroma may be debilitating in cases where patients have difficulty walking or applying pressure on their foot out of fear of pain. The neuroma is associated with a pathology of the plantar digital nerve as it divides at the base of the toes to supply the sides of the toes. There are many different treatments that have been used for Morton’s Neuroma such as NSAIDs, corticosteroid injections, ablative procedures, and surgery.

A careful history and physical examination is considered the most important diagnostic approach and in most cases needs no further diagnostic testing.

C.14.a Treatment

C.14.a.i Rehabilitation
C.14.a.i.a Extracorporeal Shockwave Therapy

**Not Recommended** - for Morton’s Neuroma.

*Evidence for the Use of Extracorporeal Shockwave Therapy for Morton’s Neuroma*

C.14.a.i.b Manipulation or Mobilization of the Distal Lower Extremity for Treatment of Morton’s Neuroma

**Not Recommended** - for treatment of Morton’s Neuroma.

*Evidence for the Use of Manipulation and Mobilization*

C.14.a.ii Injection Therapy

C.14.a.ii.a Glucocorticosteroid Injections for Select Morton’s Neuroma

**Recommended** - for Morton’s Neuroma.

*Indications*: select cases where pain and/or debility are significant and changing shoe wear, and/or orthotics fail to sufficiently control symptoms.

*Rationale for Recommendation*: Up to three injections to attempt to reduce symptoms is a reasonable intervention to try before surgery. Ongoing injections are not recommended.

*Evidence for the use of Glucocorticosteroid Injections*

C.14.a.ii.b Sclerosant Injections for Morton’s Neuroma

**Not Recommended** - for Morton’s Neuroma.

C.14.a.iii Surgery

C.14.a.iii.a Ablation for Morton’s Neuroma

**Recommended** - for Morton’s Neuroma.

*Indications*: Select cases where pain and/or debility are significant and changing shoe wear, orthotics and glucocorticoid injection(s) fail to sufficiently control symptoms.

C.14.a.iii.b Surgical Excision and/or Decompression for Morton’s Neuroma
**Recommended** - where pain and/or debility are significant and changing shoe wear, orthotics and glucocorticoid injection(s) fail to sufficiently control symptoms.

*Rationale for Recommendations:* Ablative procedures or surgery are recommended in select cases where pain and/or debility are significant and changing shoe wear, orthotics and glucocorticoid injection(s) fail to sufficiently control symptoms.

*Evidence of the Use of Surgery*

**C.14.a.iv Other**

**C.14.a.iv.a Changes in Shoewear for Treatment of Morton’s Neuroma**

**Recommended** - for treatment of Morton’s Neuroma.

*Indications:* Essentially all patients should be advised to wear stiff-soled, wide toe box shoes with a low heel and soft insert.

**C.14.a.iv.b Orthotics for Treatment of Morton’s Neuroma**

**Recommended** - for treatment of Morton’s Neuroma.

**C.14.a.iv.c Metatarsal Pads for Treatment of Morton’s Neuroma**

**Recommended** - for treatment of Morton’s Neuroma.

*Rationale for Recommendation:* An attempt at an orthosis or a metatarsal pad is recommended.

*Evidence for use of Orthotics*

---

**C.15 Bunions / Hallux Valgus**

Hallux valgus (“bunion”) is a lateral deviation of the great toe at the metatarsophalangeal joint with respect to the midline of the body, generally defined as over 14.5 degrees; and occurring in most cases with medial deviation of the first metatarsal.

The feet should show valgus deviation of the great toe beyond the first metatarsophalangeal joint.

**C.15.a Diagnostic Studies**

A careful history and physical examination is considered the most important diagnostic approach and in most cases needs no further diagnostic testing for preliminary treatment.
C.15.a.i X-Rays

**Recommended** – to evaluate alternate conditions such as osteoarthrosis, gout and degenerative joint disease. Also, x-rays are useful for measuring angles and surgical planning.

C.15.b Treatments

C.15.b.i Rehabilitation

C.15.b.i.a Low Intensity Ultrasound

**Not Recommended** - for postoperative osteotomy hallux valgus treatment.

Evidence for the Use of Ultrasound

C.15.b.i.b Manipulation or Mobilization for Treatment of Hallux Valgus

**Not Recommended** - for treatment of hallux valgus.

Evidence for the Use of Manipulation and Mobilization

C.15.b.ii Surgery

C.15.b.ii.a Surgery for Hallux Valgus

**Recommended** - for Hallux Valgus.

*Indications*: Select cases of mostly moderate hallux valgus where pain and/or debility are significant and changing shoe wear and orthotics fail to sufficiently control symptoms.

Evidence of the Use of Surgery

C.15.b.iii Other

C.15.b.iii.a Orthotics for Treatment of Hallux Valgus

**Recommended** - for treatment of Hallux Valgus.

*Indications*: Use of orthoses for hallux valgus should generally be limited to one of two conditions: 1) There should be demonstrable hyperpronation or radiographic evidence of hyperpronation with a talar flexion angle of 30 degrees or more on a standing study; or 2) there should be pain localized to the plantar aspect of the hallux metatarsal head with or without bunion pathology.
Rationale for Recommendation: Orthotics are recommended for those with symptoms insufficiently controlled by changing shoewear when possible.

Evidence for Use of Orthotics

C.16 Hammer Toe

Hammer toe syndromes normally occur in the sagittal plane. The metatarsophalangeal joint is dorsiflexed, while the proximal interphalangeal joint is plantarflexed. Hammer toe mostly affects the second toe.

C.16.a Treatment

C.16.a.i Non-Operative Treatments Include Footwear Modifications to Improve Toe Box/Room, Padding, Corticosteroid Injections, and Orthoses.

Recommended – for treatment of hammer toe.

C.16.a.ii Operative Treatment (Arthroplasty, Flexor Tendon Transfer, Flexor Tenotomy, Extensor Tendon Lengthening and Metatarsophalangeal Joint Capsulotomy, Fusion, and Diaphysectomy)

Recommended – for hammer toes with insufficient results from non-operative procedures.

C.17 Ankle and Foot Fractures

The initial evaluation of a patient with ankle injury should seek to identify conditions that require immediate treatment. These conditions include open fracture, vascular compromise, compartment syndrome, and joint dislocation.

In general, undisplaced or minimally displaced injuries are treated non-operatively, whereas displaced or unstable injuries are treated operatively. Complications of ankle and foot fractures include decreased range of motion, post-traumatic osteoarthritis, pain, persistent pain despite hardware removal, progressive talar instability, and malunions with concomitant syndesmotic widening.

The initial treatment of foot and ankle fractures is dictated by injury type (displaced or stable, open or closed) and by concomitant soft tissue injury. Closed, stable injuries are generally treated non-operatively. Open fractures require emergent debridement and antibiotic prophylaxis. Closed unstable fractures generally require operative management. Management should be initiated for severe swelling, compartment syndrome, and skin integrity breakdown from fracture blisters.
C.17.a Diagnostic Studies

C.17.a.i X-Ray for Suspected Acute Ankle Fractures

**Recommended** – as a first-line study.

*Indications:* Suspicion of fracture.

*Rationale for Recommendation:* X-ray is the recommended initial imaging study for suspected fracture.

*Evidence for the Use of Ottawa Ankle and Foot Rules for Ankle Sprain*

C.17.a.ii MRI for Distal Lower Extremity and Ankle Fractures

**Recommended** – for investigation of distal lower extremity and ankle fractures.

*Indications:* For acute or subacute fracture to evaluate soft tissue/ligament trauma in complex displaced or comminuted fracture, or if stability of fracture is uncertain and MRI will guide management decision.

*Rationale for Recommendation:* MRI should not be used as a first-line imaging technique. Upon confirmation of displaced, comminuted, or unstable fracture, MRI may be an important diagnostic technique for the evaluation of suspected injuries of soft tissues related to distal fibular, tibial, and malleolar fractures, such as to the syndesmotic ankle ligament complex, extensor tendons, deltoid ligament, or tibial nerve. MRI is recommended for these select circumstances.

*Evidence for the Use of MRI for Evaluation of Ankle Fractures*

C.17.a.iii CT for Diagnosis and Classification of Ankle Fractures

**Recommended** – for investigation of distal lower extremity and ankle fractures.

*Indications:* Suspected occult and complex ankle fractures; to gain greater clarity of fracture displacement. If intraarticular displacement is considered, then axial views are recommended in addition to any coronal views.

*Rationale for Recommendation:* CT should be considered when x-ray images are negative, but on the basis of physical findings, an occult fracture is strongly suspected. CT may also be useful for evaluation of complex comminuted fractures, providing superior depiction of distal tibial articular surface involvement, fragment positioning, and diagnosis of subluxations.

*Evidence for the Use of CT for Evaluation of Ankle Fractures*
C.17.a.iv Ultrasound Imaging for Diagnosing Ankle Fracture

**Recommended** – for evaluation of soft-tissue injury associated with select displaced fractures or suspected malleolar stress fractures.

**Indications:** Evaluation of soft-tissue injury associated with select displaced fractures to assess stability of fracture, particularly of the deltoid ligaments with medial and bimalleolar fractures, and in detection of suspected occult or stress fractures. Also used for suspected stress fracture of the distal tibia.

**Rationale for Recommendation:** Ultrasound imaging may be a useful adjuvant to clinical assessment of patients with regards to selection for further radiological examination, and is therefore recommended in select patients.

**Evidence for the Use of Ultrasound for Evaluation of Ankle Fractures**

C.17.b Medications

C.17.b.i Pre-Operative Antibiotic Prophylaxis for Ankle Fractures

**Recommended** – for closed or open ankle fracture surgery.

**Evidence for the Use of Antibiotic Prophylaxis for Ankle Fractures**

C.17.b.ii Use of Nasal Spray Calcitonin for Post-fracture Osteopenia

**Not Recommended** – for prophylaxis of post-fracture osteopenia.

**Evidence for the Use of Calcitonin Prophylaxis for Post-fracture Osteopenia**

C.17.b.iii DVT Prophylaxis

See discussion of DVT prophylaxis in the Achilles tendon rupture section.

**Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) and Acetaminophen**

For most patients, ibuprofen, naproxen, or other older generation NSAIDs are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence suggests acetaminophen is modestly less effective. There is evidence that NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.

C.17.b.iv Non-Steroidal Anti-inflammatory Drugs (NSAIDs) for Acute Ankle Fracture Analgesia

**Recommended** - for treatment of pain associated with ankle fracture.
Indications: For acute, subacute, chronic, or postoperative ankle fracture, NSAIDs are recommended for treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

Frequency/Duration: As needed use may be reasonable for many patients.

Indications for Discontinuation: Resolution of foot/ankle pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.

C.17.b.v NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding

Recommended - concommiment use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine Type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

Indications: For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.

Frequency/Dose/Duration: Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding.

Indications for Discontinuation: Intolerance, development of adverse effects, or discontinuation of NSAID.

C.17.b. vii NSAIDs for Patients at Risk for Cardiovascular Adverse Effects

Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.

Recommended - Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse.

Recommended - If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to minimize the potential for the NSAID to counteract the beneficial effects of aspirin, the NSAID should be taken at least 30 minutes after or eight hours before the daily aspirin.

C.17.b.vii Acetaminophen for Treatment of Acute, Subacute, or Chronic Acute Ankle Fracture Pain

Recommended - for treatment of acute, subacute, or chronic acute ankle fracture pain, particularly in patients with contraindications for NSAIDs.
Indications: All patients with foot/ankle pain, including acute, subacute, chronic, and postoperative.

Dose/Frequency: Per manufacturer's recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

Indications for Discontinuation: Resolution of pain, adverse effects or intolerance.

Evidence for the Use of NSAIDs and Acetaminophen for Foot and Ankle Fractures

C.17.b.viii Limited Use of Opioids for Acute and Postoperative Pain Management

Recommended – for limited use (less than seven days) for acute and postoperative pain management as adjunctive therapy to more effective treatments.

Indications: For acute injury and postoperative pain management, a brief prescription of opioids as adjuncts to more efficacious treatments (especially NSAIDs, acetaminophen, elevation, splinting) is often required, especially nocturnally.

Frequency/Duration: Prescribed as needed throughout the day, then later only at night, before weaning off completely.

Rationale for Recommendation: Some patients have insufficient pain relief with NSAIDs, thus judicious use of opioids may be helpful, particularly for nocturnal use. Opioids are recommended for brief, select use in postoperative patients with primary use at night to achieve sleep postoperatively.

Evidence for the Use of Opioids for Foot and Ankle Fractures

C.17.b.ix Tetanus Immunization Status for Open Fractures

Recommended – updating of tetanus immunization status as necessary.

Indications: Wounds that are not clean if more than five years have elapsed since last tetanus immunization.

Rationale for Recommendation: As the adverse effects of not immunizing may be fatal, tetanus immunization updating for open wounds is recommended. Wounds that are not clean or burns should require immunization if more than five years since last immunization, rather than ten years. Patients without a completed immunization series of three injections should receive tetanus immune globulin along with immunization.
Evidence for the Use of Tetanus Immunization for Open Foot and Ankle Fractures

C.17.b.x Analgesia for Non-Operative Reduction Ankle Fractures

**Recommended** – for performing non-operative closed reduction of ankle fractures.

*Rationale for Recommendation:* Appropriate technique should be based on factors of physician experience and preference, patient history of intolerance to medications or level of anxiety, and availability of equipment and supplies.

Evidence for the Use of Non-operative Reduction Analgesia for Ankle Fractures

C.17.c Treatments

C.17.c.i Mobilization / Immobilization

C.17.c.i.a Cast Immobilization for Ankle Fractures

**Recommended** - for the management of ankle fractures.

*Indications:* All ankle fractures.

*Frequency/Duration:* Immobilization generally for six to eight weeks.

*Rationale for Recommendation:* Cast immobilization is recommended for all patients and the use is dependent on physician and patient preference.

C.17.c.i.b Early Mobilization for Ankle Fractures

**Recommended** - in the management of postoperative and stable non-operative ankle fractures.

*Indications:* Stabilized malleolar fractures with or without surgery and closed ankle fractures with adequate fixation and stabilization.

*Frequency/Duration:* Early mobilization can be started within one to three days postoperatively.

*Rationale for Recommendation:* Early mobilization is recommended for most patients with stable or repaired malleolar ankle fracture.

C.17.c.i.c Early Postoperative Weight-bearing for Ankle Fractures

**Recommended** - Early weight-bearing of operatively fixated ankle fractures postoperatively.
**Indications:** Stabilized malleolar fractures with or without surgery and closed ankle fractures with adequate fixation and stabilization.

**Rationale for Recommendation:** Early weight-bearing may provide improvement in functional recovery short-term, does not appear to result in increased adverse events.

**Evidence for the Use of Immobilization, Early Mobilization, Early Weight-bearing for Ankle Fractures**

---

**C.17.c.ii Rehabilitation**

**C.17.c.ii.a Electrical Stimulation for Prevention of Muscle Atrophy**

*Not Recommended* - for prevention of muscle atrophy in ankle and foot fracture management.

**Evidence for the Use of Electrical Stimulation for Ankle and Foot Fractures**

**C.17.c.ii.b Therapy for Patients with Functional Deficits after Cast Removal**

*Recommended* - after cast removal for ankle fractures.

**C.17.c.ii.c Manual Therapy as Part of a Post-ankle Fracture Rehabilitation Program**

*Recommended* - as part of an active post-ankle fracture rehabilitation program.

**C.17.c.ii.d Passive Stretching for Contractures After Immobilization of Ankle Fractures**

*Not Recommended* - for contractures after immobilization of ankle fractures.

*Frequency/Dose/Duration:* Frequency of visits is usually individualized based on severity of the limitation. Two to three visits per week for two weeks are often used to initiate an exercise program. Total numbers of visits may be as few as two to three for mild deficits or for more severe deficits, up to 12 to 15 with documentation of objective functional improvement.

**Evidence for the Use of Therapy for Ankle Fractures**

**C.17.c.ii.e Ultrasound to Stimulate Bone Healing for Ankle and Foot Fractures**

---

NYS WCB MTG – Ankle and Foot Disorders  98
Not Recommended - for ankle and foot fracture management.

Evidence for the Use of Ultrasound Stimulation for Ankle and Foot Fractures

C.17.c.ii.f Hyperbaric Oxygen for the Management of Ankle or Foot Fractures

Not Recommended - for management of ankle or foot fractures.

Evidence for the Use of Hyperbaric Oxygen for Ankle and Foot Fractures

C.17.c.iii Fracture Care

Malleolar Ankle Fractures
Management of non-displaced and stable fractures has traditionally been non-operative with good results. There is continued debate regarding treatment for particular fractures types that are not clearly stable or unstable. Non-union of the distal fibula fracture is rare lending support to a trial of conservative management for non-displaced and stable displaced fractures. Reduction failure or delayed union may require surgical intervention. Posterior malleolar fractures are often missed and are highly variable.

C.17.c.iii.a Immobilization for Non-displaced Ankle Fractures

Recommended - for the treatment of non-displaced and reduced stable ankle fractures.

C.17.c.iii.b Immobilization and Reduction for Closed Displaced Ankle Fractures

Recommended – for select non-comminuted closed displaced ankle fractures.

Indications: Non-comminuted closed displaced ankle fractures with post-reduction displacement less than two to three mm and less than 25% posterior malleolus articular surface involvement.

C.17.c.iii.c Operative Fixation for Closed Displaced Ankle Fractures

Recommended – for unstable closed displaced ankle fractures.

Indications: Generally severe lateral fracture with medial malleolar involvement. Comminuted closed displaced ankle fractures with post-reduction displacement more than 2 to 3mm and more than 25% posterior malleolus articular surface involvement
Rationale for Recommendations: In the absence of severe systemic comorbidities, the results after open reduction and internal fixation of malleolar fractures in patients above and below 60 years of age are nearly identical, while nonoperative treatment of unstable fractures leads to significantly inferior outcomes. Therefore, the general indications for surgery in elderly patients should not differ from those in younger patients. Individual fracture treatment is tailored depending on bone quality, skin conditions, comorbidities and functional demand of the patient. To avoid complications, it is imperative to consider and treat comorbidities such as diabetes and osteoporosis.

Evidence for the Management of Malleolar Ankle Fractures

Tibial Shaft Fractures (Diaphyseal)

C.17.c.iii.d Operative Fixation for Tibial Shaft Fracture (Closed, Diaphyseal)

Recommended – for definitive management of displaced tibial shaft fracture.

Indications: Displaced, comminuted distal tibial shaft fracture.

C.17.c.iii.e Cast Immobilization for Tibial Shaft Fractures (Closed, Diaphyseal)

Recommended – case may be indicated in select patients with closed, stable, tibial fracture.

Evidence for the Management of Tibial Shaft Fractures

Distal Tibial Extra-Articular Fractures

C.17.c.iii.f Operative Fixation (i.e., Fracture Plating, Intramedullary Nail) for Distal Tibial Extra-Articular Fractures

Recommended – in select patients.

Indications: Open fractures, initial shortening >15mm, angular deformity after initial manipulation >5° in any plane.

C.17.c.iii.g Cast Immobilization for Distal Tibial Extra-Articular Fractures

Recommended – in select circumstances for distal extra-articular tibial fractures.
Indications: Closed simple fractures with initial shortening <15mm, angular deformity after initial manipulation <5° in any plane.

Evidence for the Management of Tibial Extra-articular Fractures

Tibial Plafond (Pilon) Fractures

C.17.c.iii.h Non-operative Management of Tibial Plafond and Pilon Fractures

Recommended – in select patients.

Indications: Non-displaced, non-comminuted, stable fracture; ability to obtain acceptable fracture alignment with closed reduction.

C.17.c.iii.i Operative Management of Tibial Plafond and Pilon Fractures

Recommended – for tibial plafond fractures in select patients.

Indications: Displaced, comminuted, or inability to obtain acceptable fracture alignment with closed reduction.

Rationale for Recommendations: Distal lower leg fractures that impinge on the articular surface with the talus are known as plafond fractures. These fractures are noted to have high complication rates from surgical reduction and fixation.

Evidence for the Management of Tibial Plafond and Pilon Fractures

Syndesmotic Ruptures

Operative treatment of unstable syndesmotic injury to restore the tibiofibular relationship.

C.17.c.iii.j Operative Fixation for Syndesmotic Ruptures

Recommended - for unstable syndesmotic rupture.

Indications – Closed ankle fractures with unstable syndesmosis, AO fracture type C and/or pathologic widening of more than 2mm of the syndesmosis at intra-operative testing.

C.17.c.iii.k Non-operative Management of Syndesmotic Injuries

Recommended - for stable syndesmotic injury.
**Indications:** Absence of other destabilizing injury including ankle fracture or deltoid ligament injury.

**Rationale for Recommendations:** There is opinion that not all ankle syndesmotic injuries lead to ankle instability, and may not need repair in the absence of other destabilizing injury. Fixation is required in the presence of fracture. Thus, non-operative management is recommended for select patients. Operative repair is recommended for non-stable injuries, which include most syndesmotic rupture with concurrent fractures or deltoid ligament injury.

**Evidence for the Treatment of Syndesmotic Injury**

**Fibular Fracture**

C.17.c.iii.l **Operative Fixation for Displaced Distal Fibula Fractures**

**Recommended** - for displaced distal fibula fracture.

**Indications:** Distal fibula shaft fracture, unsatisfactory closed reduction.

**Rationale for Recommendation:** Operative fixation is recommended for displaced, unstable distal fibular fractures.

**Evidence for the Operative Management of Fibular Shaft Fractures**

**Arthroscopy with ORIF of Distal Fibular Fractures**

C.17.c.iii.m **Use of Arthroscopy Assisted ORIF for Distal Fibular Fractures**

**Not Recommended** - for distal fibular fractures.

**Evidence for the Use of Arthroscopy Evaluation During Distal Tibia Fracture Fixation ORIF**

**Deltoid Ligament Repair with ORIF of Lateral Ankle Fracture**

C.17.c.iii.n **Deltoid Ligament Repair Concurrent with ORIF for Unstable Ankle Fractures**

**Recommended** – for patients with deltoid ligament disruption and high fibular fractures or in patients with concomitant syndesmotic fixation.

**Evidence for the Repair of Deltoid Ligament with Lateral Ankle Fracture Fixation**

C.17.c.iv **Other**
C.17.c.iv.a Pneumatic Compression for Treatment of Ankle and Foot Edema

**Recommended** - for patients with significant postoperative edema.

*Indications:* Excessive swelling after ankle fracture surgery.

*Evidence for the Use of Pneumatic Compression for Edema Management*

C.17.c.iv.b Interferential Therapy for Treatment of Ankle Edema

**Not Recommended** - for the treatment of postoperative swelling following ORIF for displaced malleolar fracture.

*Evidence for the Use of Interferential Current Therapy for Postoperative Edema Management*

C.18 Hindfoot Fractures (Calcaneus, Talus)

C.18.a Diagnostic Studies

C.18.a.i X-ray

**Recommended** - as a first-line study for suspected acute hindfoot fractures.

*Indications:* Suspicion of fracture.

*Views:* Calcaneus: AP, lateral, and calcaneal view; Talus: AP, lateral, mortise, Broden views (45° internal oblique) and Canale views (talar neck).

*Evidence for the Use of X-ray for Hindfoot Fractures*

C.18.a.ii MRI

**Recommended** - for suspected acute occult fracture of the talus and calcaneus.

*Indications* – Generally reserved for suspicion of occult fracture of the talus neck or lateral process. Patients whose plain images indicate osteochondral lesion and those who remain symptomatic after six weeks should undergo evaluation with MRI.

C.18.a.iii MRI for Follow-up Evaluation of Non-acute Calcaneus Fracture
**Recommended** - for calcaneus fractures for identification of complications in the non-acute fracture patient.

*Indications*: Non-acute fracture patient with persistent pain more than four months after injury.

*Rationale for Recommendations*: MRI is used for suspected occult fracture, as some talus fractures are not apparent on radiographs. MRI is also indicated for evaluation of avascular necrosis. In general, MRI is suboptimal compared with CT scan for calcaneus injury.

*Evidence for the Use of MRI for Hindfoot Fractures*

**C.18.a.iv Bone Scanning for Calcaneus Fracture**

**Recommended** - for diagnosis of occult and stress fractures in select patients.

*Rationale for Recommendation*: A bone scan may be reasonable for those with high clinical suspicion but with negative x-ray and CT scan. Bone scans are utilized to diagnose occult calcaneus fractures and stress fractures of the calcaneus.

*Evidence for the Use of Bone Scanning for Hindfoot Fractures*

**C.18.a.v CT for Diagnosis and Classification of Hindfoot Fractures**

**Recommended** - for investigation of hindfoot fractures.

*Indications*: CT is recommended for occult and complex distal extremity, ankle, and foot fractures to gain greater clarity of fracture displacement, articular involvement, and subluxation of affected joints. If intraarticular displacement is considered, then axial views are recommended in addition to any coronal views. CT is indicated for evaluation of suspected subtalar joint fractures.

*Views*: Coronal and axial.

*Rationale for Recommendation*: CT scans are considered the gold standard for diagnosing and characterizing calcaneus fractures. For other hindfoot fractures, CT should be considered when x-ray images are negative, but on the basis of physical findings an occult fracture is strongly suspected. CT may also be useful for evaluation of complex comminuted fractures, providing superior depiction of distal tibial articular surface involvement, fragment positioning, and diagnosis of subluxations. The value of CT has been demonstrated – its use for evaluation of articular step off and gaping, comminution, and treatment has influenced observers to change treatment plans developed from radiographs.

*Evidence for the Use of CT for Hindfoot Fractures*
C.18.a.vi Follow-up Visits – Imaging
For talus fracture, if clinically suspected in the setting of negative radiographs, follow-up radiographs may be helpful; after approximately seven days there will be resorption at the fracture line, which will then be visible more easily. Follow-up radiography at six to eight weeks for confirmed talus fracture, looking for the Hawkins sign, a radiographic subchondral radiolucent band in the talar dome. This sign, visible in the anterior-posterior view, is indicative of viability at six to eight weeks post-fracture indicating that avascular necrosis is unlikely to develop.

C.18.b Medications

Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) and Acetaminophen
For most patients, ibuprofen, naproxen, or other older generation nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence suggests acetaminophen is modestly less effective. There is evidence that NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.

C.18.b.i Non-Steroidal Anti-inflammatory Drugs (NSAIDs) and Acetaminophen for Hindfoot Fractures Analgesia

**Recommended** - for hindfoot fracture analgesia.

*Indications:* For hindfoot fracture analgesia, NSAIDs are recommended for treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

*Frequency/Duration:* As needed use may be reasonable for many patients.

*Indications for Discontinuation:* Resolution of foot/ankle pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.

C.18.b.ii NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding.

**Recommended** – concomitant use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine Type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

*Indications:* For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.
Frequency/Dose/Duration – Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding.

Indications for Discontinuation – Intolerance, development of adverse effects, or discontinuation of NSAID.

C.18.b.iii NSAIDs for Patients at Risk for Cardiovascular Adverse Effects

Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.

Recommended - Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse.

Recommended - If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to minimize the potential for the NSAID to counteract the beneficial effects of aspirin, the NSAID should be taken at least 30 minutes after or 8 hours before the daily aspirin.

C.18.b.iv Acetaminophen for Treatment of Hindfoot Fracture Pain

Recommended - for treatment of hindfoot fracture pain, particularly in patients with contraindications for NSAIDs.

Indications: All patients with foot/ankle pain, including acute, subacute, chronic, and postoperative.

Dose/Frequency: Per manufacturer’s recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

Indications for Discontinuation: Resolution of pain, adverse effects or intolerance.

Evidence for the Use of NSAIDs and Acetaminophen for Foot and Ankle Fractures

C.18.b.v Limited Use of Opioids for Acute and Postoperative Pain Management

Recommended – for limited use (less than seven days) in select patients for acute and postoperative pain management as adjunctive therapy to more effective treatments.

Indications: For acute injury and postoperative pain management, a brief prescription of opioids as adjuncts to more efficacious treatments (especially NSAIDs, acetaminophen, elevation, splinting) is often required, especially nocturnally.
Frequency/Duration: Prescribed as needed throughout the day, then later only at night, before weaning off completely.

Rationale for Recommendation: Select patients have insufficient pain relief with NSAIDs, thus judicious use of opioids may be helpful, particularly for nocturnal use. Opioids are recommended for brief, select use in postoperative patients with primary use at night to achieve sleep postoperatively.

Evidence for the Use of Opioids for Foot and Ankle Fractures

C.18.b.vi Tetanus Immunization Status for Open Fractures

Recommended – updating of tetanus immunization status as necessary.

Indications: Wounds that are not clean if more than five years have elapsed since last tetanus immunization.

Rationale for Recommendation: As the adverse effects of not immunizing may be fatal, tetanus immunization updating for open wounds is recommended. Wounds that are not clean or burns should require immunization if more than five years since last immunization, rather than ten years. Patients without a completed immunization series of three injections should receive tetanus immune globulin along with immunization.

Evidence for the Use of Tetanus Immunization for Open Foot and Ankle Fractures

C.18.b.vii Pre-Operative Antibiotic Prophylaxis for Ankle Fractures

Recommended – for closed or open ankle fracture surgery.

Evidence for the Use of Antibiotic Prophylaxis for Ankle Fractures

C.18.b.viii Use of Nasal Spray Calcitonin for Post-fracture Osteopenia

Not Recommended – for prophylaxis of post-fracture osteopenia.

Rationale for Recommendation: Nasal calcitonin obtained from salmon compared with placebo did not result in significant differences in bone mineralization 3 months after surgery.

Evidence for the Use of Calcitonin Prophylaxis for Post-fracture Osteopenia

C.18.b.ix DVT Prophylaxis

See discussion of DVT prophylaxis in the Achilles tendon rupture section.
C.18.c Treatments

C.18.c.i Rehabilitation

Therapy
Rehabilitation (supervised formal therapy) required as a result of a work-related injury should be focused on restoring functional ability required to meet the patient’s daily and work activities and return to work; striving to restore the injured worker to pre-injury status in so far as is feasible.

Active therapy requires an internal effort by the patient to complete a specific exercise or task. Passive therapy are those interventions not requiring the exertion of effort on the part of the patient, but rather are dependent on modalities delivered by a therapist. Generally passive interventions are viewed as a means to facilitate progress in an active therapy program with concomitant attainment of objective functional gains. Active interventions should be emphasized over passive interventions.

The patient should be instructed to continue both active and passive therapies at home as an extension of the treatment process in order to maintain improvement levels.

Assistive devices may be included as an adjunctive measure incorporated into the rehabilitation plan to facilitate functional gains.

C.18.c.i.a Diathermy for Management of Edema Associated with Calcaneus Fracture

Not Recommended - for management of edema associated with calcaneus fractures.

Evidence for the Use of Diathermy for Edema Control

C.18.c.i.b Therapeutic Exercise - Physical / Occupational Therapy

Recommended – to improve function, including range of motion and strength.

Frequency/Dose/Duration –Total numbers of visits may be as few as two to three for patients with mild functional deficits or up to 12 to 15 with more severe deficits with documentation of ongoing objective functional improvement.

When there are ongoing functional deficits, more than 12 to 15 visits may be indicated if there is documentation of functional improvement towards specific objective functional goals (e.g., range of motion, advancing ability to perform work activities). As part of the rehabilitation plan a home exercise program should be developed and performed in conjunction with the therapy.
C.18.c.ii Fracture Care

**Talus Fractures**
Because of its key position, diagnosis and treatment of talus fractures is critical for foot and ankle function.

**C.18.c.ii.a Non-operative Management of Non-displaced Talar Fractures**

*Not Recommended* - for non-displaced talar fractures (head, neck, body).

**C.18.c.ii.b Operative Management of Displaced Talar Fractures**

*Recommended* - for all displaced talar fractures (head, neck, body, lateral process).

**Indications:** All non-displaced, non-reducible fractures. Referral to specialist is indicated for all injuries due to the high potential for poor outcomes of these injuries. Emergent referral for talar neck fractures.

**Rationale for Recommendations:** Because of the key role the talus plays in locomotion, and the risk for significant disability and complication with these fractures referral to specialists for most, if not all, talus fractures is recommended.

**Evidence for the Management of Talar Fractures**

**Osteochondral Lesions of the Talus**

**C.18.c.ii.c Non-Operative Management of Osteochondral Lesions of the Talus**

*Recommended* - for select patients.

**Indications:** A non-operative approach is indicated for initial management of lateral lesions that radiographically appear to be a compression lesion with no visible fragment or there is a fragment but it is still attached.

**Management:** Cast or brace immobilization and protected weight-bearing for six to 12 weeks, followed by increasing pain-free range-of-motion exercises and strengthening.

**C.18.c.ii.d Operative Intervention for Osteochondral Lesions of the Talus**
**Recommended** - after an initial course of conservative management. Microfracture and osteochondral autograft are recommended.

*Rationale for Recommendations*: A trial of conservative management is recommended initially. A trial of protected weight bearing for six to 12 weeks is reasonable.

*Evidence for the Use of Operative Management for Osteochondral Lesions*

**Calcaneus Fractures**

**C.18.c.ii.e  Cast Immobilization for Select Calcaneus Fractures**

**Recommended** - for select calcaneus fractures.

*Indications*: Non-displaced fracture, displaced extra-articular, displaced intra-articular.

**C.18.c.ii.f  Operative Management for Select Calcaneus Fractures**

**Recommended** - for select calcaneus fractures.

*Indications*: Displaced, non-reducible extra-articular fractures, displaced intra-articular fractures.

*Rationale for Recommendations*: Both operative and non-operative management have considerable potential for adverse effects, including secondary late fusion, compartment syndrome and fasciotomy, DVT and pulmonary embolism, and late-term arthrodesis.

*Evidence for the Management of Calcaneal Fractures*

**C.18.c.iii Other**

**C.18.c.iii.a  Use of Pneumatic Compression Device for Treatment of Calcaneus Fractures**

**Recommended** - for patients with significant edema after closed calcaneus fractures.

*Indications*: Patients with excessive swelling after closed displaced calcaneus fractures who are surgical candidates. Use in non-operative patients to reduce risk of other complications.

*Frequency/Duration*: Pedal compression device used continuously until swelling subsides sufficiently to allow for surgery or to manage non-operatively.
Rationale for Recommendation: Pneumatic compression for edema management is recommended for management of acute calcaneus fracture management in select patients with significant edema.

Evidence for the Management of Edema Associated with Calcaneal Fractures

C.19 Forefoot and Midfoot Fractures (Tarsal, Metatarsal, Phalangeal)

C.19.a Diagnostic Studies

C.19.a.i X-ray for Suspected Acute Forefoot or Midfoot Fractures

**Recommended** - as a first-line study for suspected forefoot or midfoot fractures.

*Indications:* Suspicion of all forefoot and midfoot fractures.

*Views:* AP, lateral, and oblique.

*Rationale for Recommendation:* X-ray assists in identifying fractures, orientation of fracture plane(s), magnitude of the involvement of the interphalangeal and metatarsal phalangeal joints, which if large enough may alter management in favor of surgery (see below). If fracture is clinically suspected in the setting of negative radiographs, follow-up radiographs may be helpful; after approximately seven days there will be resorption at the fracture line, which will then be visible.

Evidence for the Use of X-ray for Suspected Tarsal, Metatarsal, or Phalangeal Fractures

C.19.a.ii MRI for Suspected Acute Forefoot and Midfoot Fractures

**Recommended** - for suspected occult and stress fracture in select patients.

*Indications:* Generally reserved for suspicion of occult or stress fracture of the fore or midfoot, however, CT is viewed as superior by some.

*Rationale for Recommendation:* MRI should not be used as a first-line test. MRI may be an important diagnostic technique for the evaluation of suspected injuries of the navicular, tarsometatarsal joint (Lisfranc injury) and for early diagnosis of suspected stress fracture. MRI is also used for suspected occult fracture and for evaluation of avascular necrosis.

Evidence for the Use of MRI for Suspected Tarsal Metatarsal and Phalangeal Fractures

C.19.a.iii Bone Scanning for Forefoot and Midfoot Fractures

**Recommended** - for diagnosis of occult and stress fractures in select patients.
Indications: Generally reserved for suspicion of occult fracture of the tarsal and metatarsal bones.

Rationale for Recommendation: Bone scans are not required for evaluation of the majority of patients with forefoot and midfoot fractures. A bone scan may be reasonable for patients with high clinical suspicion but negative x-ray or CT scan.

Evidence for the Use of Bone Scan for Suspected Tarsal, Metatarsal, or Phalangeal Fractures

CT Imaging

C.19.a.iv CT for Diagnosis and Classification of Forefoot and Midfoot Fractures

Recommended – in select patients for investigation of forefoot and midfoot fractures.

Indications: Evaluation of displaced or comminuted fracture of the tarsal and metatarsal bones to gain greater clarity of fracture displacement, articular involvement, and subluxation of affected joints. Generally, this is a second-line diagnostic tool after x-rays.

Rationale for Recommendation: CT should not be used as a first-line test. CT may be an important diagnostic technique to gain greater clarity of fracture displacement, articular involvement, and subluxation of affected joints, and is recommended for select patients.

Evidence for the Use of CT for Suspected Tarsal Metatarsal and Phalangeal Fractures

C.19.b Medications

Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) and Acetaminophen

For most patients, ibuprofen, naproxen, or other older generation nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended as first-line medications. Acetaminophen (or the analog paracetamol) may be a reasonable alternative to NSAIDs for patients who are not candidates for NSAIDs, although most evidence suggests acetaminophen is modestly less effective. There is evidence that NSAIDs are as effective for relief of pain as opioids (including tramadol) and less impairing.

C.19.b.i Non-Steroidal Anti-inflammatory Drugs (NSAIDs) and Acetaminophen for Phalangeal or Metatarsal Fracture Pain Control

Recommended - for phalangeal or metatarsal fracture pain control.

Indications: For acute, subacute, chronic, or postoperative phalangeal or metatarsal fracture pain control, NSAIDs are recommended for
treatment. Over-the-counter (OTC) agents may suffice and should be tried first.

*Frequency/Duration:* As needed use may be reasonable for many patients.

*Indications for Discontinuation:* Resolution of foot/ankle pain, lack of efficacy, or development of adverse effects that necessitate discontinuation.

**C.19.b.ii NSAIDs for Patients at High-Risk of Gastrointestinal Bleeding.**

**Recommended** – concomitant use of cytoprotective classes of drugs: misoprostol, sucralfate, histamine Type 2 receptor blockers, and proton pump inhibitors for patients at High-Risk of gastrointestinal bleeding.

*Indications:* For patients with a high-risk factor profile who also have indications for NSAIDs, cytoprotective medications should be considered, particularly if longer term treatment is contemplated. At-risk patients include those with a history of prior gastrointestinal bleeding, elderly, diabetics, and cigarette smokers.

*Frequency/Dose/Duration:* Proton pump inhibitors, misoprostol, sucralfate, H2 blockers recommended. Dose and frequency per manufacturer. There is not generally believed to be substantial differences in efficacy for prevention of gastrointestinal bleeding.

*Indications for Discontinuation:* Intolerance, development of adverse effects, or discontinuation of NSAID.

**C.19.b.iii NSAIDs for Patients at Risk for Cardiovascular Adverse Effects**

Patients with known cardiovascular disease or multiple risk factors for cardiovascular disease should have the risks and benefits of NSAID therapy for pain discussed.

**Recommended** - Acetaminophen or aspirin as the first-line therapy appear to be the safest regarding cardiovascular adverse.

**Recommended** - If needed, NSAIDs that are non-selective are preferred over COX-2 specific drugs. In patients receiving low-dose aspirin for primary or secondary cardiovascular disease prevention, to minimize the potential for the NSAID to counteract the beneficial effects of aspirin, the NSAID should be taken at least 30 minutes after or eight hours before the daily aspirin.

**C.19.b.iv Acetaminophen for Treatment of Acute, Subacute, or Chronic Phalangeal or Metatarsal Fracture Pain**

**Recommended** - for treatment of acute, subacute, or chronic phalangeal or metatarsal fracture pain, particularly in patients with contraindications for NSAIDs.
Indications: All patients with foot/ankle pain, including acute, subacute, chronic, and postoperative.

Dose/Frequency: Per manufacturer’s recommendations; may be utilized on an as-needed basis. There is evidence of hepatic toxicity when exceeding four gm/day.

Indications for Discontinuation: Resolution of pain, adverse effects or intolerance.

C.19.c Treatments

C.19.c.i Fracture Care

C.19.c.i.a Non-operative Management for Non-Displaced Tarsal-Metatarsal Injury (Lisfranc)

Recommended - for select patients.

Indications: Fracture/joint dislocation displacement <2mm.

Management: Non-weight bearing cast for six weeks.

C.19.c.i.b Operative Management for Displaced Tarsal-Metatarsal Injury (Lisfranc)

Recommended - for an unstable tarsal-metatarsal injury.

Indications: Fracture joint displacement with joint dislocation >2 mm.

Management: May take four to five months to heal; therapy may be started. Removal of hardware prior to full activities.

Rationale for Recommendations: Immobilization or fixation technique is dictated by the physical and radiographic findings.

Evidence for the Management of Lisfranc Injuries

C.19.c.i.c Non-Operative Management for Non-Displaced Metatarsal Fractures

Recommended - for non-displaced metatarsal fractures.

Indications: Non-displaced shaft fractures or with up to 3 to 4mm displacement in dorsal or plantar direction, angulation less than 10° dorsally.

C.19.c.i.d Operative Management for Displaced Metatarsal Shaft Fractures

Recommended - for displaced metatarsal shaft fractures.
Indications: Multiple metatarsals fractured if displaced; shaft fracture near metatarsal head.

Management: Percutaneous pinning or internal fixation with screws, plates; non-weight bearing four to six weeks. Progressive weight-bearing over next four to six weeks in fracture shoe/boot or walking cast. Full weight-bearing in shoes/stiff soled shoe after radiographic evidence of union.

Rationale for Recommendations: Immobilization or fixation technique is dictated by the physical and radiographic findings.

Evidence for the Management of Metatarsal Fractures

C.19.c.i.e Non-operative Management for Proximal Fifth Metatarsal Fractures (Including Joints and Avulsion).

Recommended - for select patients.

Indications: Avulsion of tuberosity: non-displaced, <1 to 2mm step-off on articular surface or less than 30% of articular surface with cuboid; Jones Fracture: patient/provider preference.

Management: Repeat films at one and six weeks. Jones Fracture: non-weight-bearing short-leg cast immobilization for one and six weeks, followed by hard-sole shoe or walking cast until union.

C.19.c.i.f Operative Management for Fifth Displaced Metatarsal Shaft Fractures (Jones, Avulsion)

Recommended - for select patients.

Indications: Avulsion of tuberosity: displaced >1 to 2mm step-off on the articular surface or more than 30% of articular surface with cuboid; Jones Fracture: patient/provider preference.

Management: Avulsion of tuberosity: similar to other metatarsal shaft fractures treated operatively. Jones Fracture: non-weight bearing Jones splint for 2 weeks, followed by weight bearing in hard-sole shoe as tolerated.

Rationale for Recommendations: Immobilization or fixation technique is dictated by the physical and radiographic findings.

Evidence for the Management of Proximal Fifth Metatarsal Injuries
C.19.c.i.g  Immobilization for Distal, Middle, or Proximal Phalanx

**Recommended** - for treatment of select patients.

*Indications:* Closed, non-displaced or stable after reduction, involves less than 25% of articular surface.

*Management:* Closed reduction after digital or hematoma block; obtain post-reduction film, repeat at one and six weeks; splint toe with buddy taping to adjacent toe until non-tender (three to four weeks) excluding hallux. Additional immobilization with a postoperative shoe or cast-boot should be considered.

C.19.c.i.h  Operative Management for Distal, Middle, or Proximal Phalanx Fractures

**Recommended** - for treatment of select patients.

*Indications:* Displaced fractures of great toe with poor reduction, unable to hold reduction with tape splinting.

*Rationale for Recommendations:* Immobilization or fixation technique is therefore dictated by the physical and radiographic findings. It is generally limited to displaced fractures of the great toe or multiple toe fractures.

**Evidence for the Management of Phalangeal Fractures**

C.19.c.i.i  Non-operative Management for Lower Extremity Stress Fractures

**Recommended** - for low risk lower extremity stress fractures.

*Indications:* Non-displaced stress fractures.

*Management:* All non-displaced stress fractures can be treated conservatively initially.

C.19.c.i.j  Operative Management for Lower Extremity Stress Fractures

**Recommended** – for lower extremity stress fractures (including navicular stress fractures) that do not respond to non-operative management or that are displaced.

*Rationale for Recommendations:* Stress fractures respond well to activity restriction in most instances. Activity restriction is therefore recommended. Stress fractures that do not respond or that are displaced are treated operatively.
Specialists may sometimes elect to initially treat select, minimally displaced fractures non-operatively.

Evidence for the Management of Stress Fractures
Appendices

Appendix D.1 – Definitions

Bunion: See hallux valgus.

Fasciitis: Inflammation of supportive band or covering.

Hallux Valgus: Lateral deviation of the great toe at the metatarsophalangeal joint with respect to the midline of the body, generally defined as over 15° and occurring in most cases with medial deviation of the first metatarsal.

Inflammation: A tissue reaction marked by redness, warmth, swelling, and pain, usually in response to injury or infection.

Ligament: A band or sheet of strong fibrous connective tissue connecting the articular ends of bones serving to bind them together and facilitate or limit motion.

Metatarsalgia: Pain in the forefoot at one or more of the metatarsal heads.

Morton’s Neuroma (Interdigital Neuroma): A benign tumor of the neurovascular bundle of the intertarsal spaces that can be between any two distal metatarsal bones, although classically, “Morton’s neuroma” describes the specific location only between the 3rd and 4th metatarsals.

Neuroma: A benign tumor composed of nerve cells.

Paratenon: tissue filling the space between a tendon and its sheath.

Plantar Fasciitis: Pain in the plantar aspect of the heel that may also be present along the fascia of the arch of the foot determined by clinical criteria, and not clearly originating in the fascia of the plantar foot or caused by inflammation.

Retinaculum: A band or bandlike structure that holds an organ or a part in place. (Stedman Medical Dictionary 15)

Sprain: Injury, not necessarily permanent, of a ligament.
S, Grade I: overstretching or slight tearing without instability.
S, Grade II: incomplete tearing.
S, Grade III: complete tear or rupture.

Strain: Injury, not necessarily permanent, of a muscle or musculotendinous unit.
S, Grade I: overstretching or slight tearing.
S, Grade II: incomplete tearing.
S, Grade III: complete tear or rupture.

Synovitis: Inflammation of synovium.

Tendinitis or Tendonitis: Inflammation of a tendon.

Tendinosis: A chronic degenerative tendon injury, unaccompanied by redness or heat. It is associated with pain and limited movement.
Tendinopathy: Any pathology of a tendon.

ruptures

6 strand suture technique.

marker separations of plantar repaired ends or planter flexion strength measured in 3 ankle positions between both groups found.

suture technique. Consequently, we recommend a simple suture technique.”

cast immobilization post-op for 7 weeks. Data suggest comparable efficacy.

Lim 2001
Quasi-RCT
4.5
N = 66 ruptured Achilles tendons
Percutaneous vs. open repair (both groups receiving postoperative casting for mean of 12.6 weeks).

No differences in recovery duration to return activities of daily living, functional activity, sports at 8, 13, 26 weeks follow-up; 21% of open repairs had infection vs. 0% with percutaneous repair (p <0.05). No difference in re-ruptures (6% vs. 3%).

“…no difference in the numbers of re-ruptures between open and percutaneous groups, and the rate of injury to the sural nerve occurring during the repair is low, but nevertheless present.”

Randomization based on medical record number (odd/even). No baseline comparison data presented. Sparse details. Data suggest comparable results.

Aktas 2007
RCT
4.0
N = 105 acute Achilles tendon ruptures
Single end-to-end with and without augmentation (use of plantaris tendon).

AOFAS hindfoot clinical outcome scores were 96.7 in Group 1 and 98.8 in Group 2. Return to preinjury level of sport activity: 58% Group 1 vs. 89% Group 2.

“Although functional outcomes of both treatment groups were the same, the end-to-end suturing technique provided a safer and more reliable treatment with a low risk of complications in the treatment of acute Achilles’ tendon ruptures compared with the plantaris tendon augmentation technique.”

Allocation and baseline results unclear. No blinding of assessment.

Evidence for the Use of Postoperative Management for Achilles Tendon Rupture
There are 2 high- and 7 moderate-quality RCTs incorporated into this analysis.

NYS WCB MTG – Ankle and Foot Disorders 155
<p>| Pfeffer 1999 | 6.5 | N = 236 with proximal plantar fasciitis | Silicone insert vs. rubber insert vs. felt insert vs. vs. custom orthosis vs. stretching only. Each group performed Achilles and plantar fascia stretching for approximately 10 minutes, twice a day. Follow-up at 8 weeks. | Percentages improved in each group: 1) silicone insert, 95%; 2) rubber insert, 88%; 3) felt insert, 81%; 4) stretching only, 72%; and 5) custom orthosis, 68%. Multivariate analysis of mean pain score changes showed all groups with significant improvement, no significant differences between groups. | &quot;We conclude that, when used in conjunction with a stretching program, a prefabricated shoe insert is more likely to produce improvement in symptoms as part of the initial treatment of proximal plantar fasciitis than a custom polypropylene orthotic device.&quot; | Lack of blinding. Study suggests added benefit from orthosis plus stretching program. However, percentages of improvement are of unknown clinical significance as benefit response included broad category of “all, much, or slightly better.” No differences in mean pain scores. |
| DiGiovanni 2003, 2006 | 4.5 | N = 101 with chronic proximal plantar fasciitis for a duration &gt;10 months | Plantar fascia tissue-stretching program vs. Achilles tendon-stretching (concentric) program; 8-week and 2-year follow-up. | Inclusion criteria was failure of non-operative treatments. Subject-relevant outcome measures all statistically better in positive responses for PF stretching vs. Achilles stretching. Overall better 82.6% vs. 55.6% (p = 0.01), &gt;50% improvement in pain 82.6% vs. 58.3% (p = 0.03). Totally satisfied 91.3% vs. 60% (p = 0.006). At 8 weeks, Achilles group switched to PF stretching. At 2-year follow-up (attrition 40%) PF &quot;After eight weeks of treatment, the group managed with plantar fascial stretching exercises exhibited enhanced outcomes with regard to pain, function, and overall satisfaction compared with those of the group managed with standard Achilles tendon-stretching exercises. This study supports the use of the tissue-specific plantar fascia-stretching protocol as the | &quot;All group received orthoses and NSAIDs. Baseline differences in duration of symptoms reported, (duration &gt;in PF group, p&lt;0.01) although the mean (years) not provided. Baseline pain scores not provided limiting comparison of change in scores (main outcome). High attrition (28%, 14/50) in Achilles stretching group. Lack of control group for Achilles limits&quot; |</p>

<td>RCT</td>
<td>167</td>
<td>Type 2 diabetes, predominantly Mexican American</td>
<td>Intervention Group: 15-min intervention designed to improve diabetes self-efficacy and foot self-care behaviors (n = 55) vs Risk Assessment Group: 5-min foot risk assessment using a monofilament (the LEAP Abbreviated Diabetes Foot Screen), designed to encourage patients’ involvement in assessing their feet (n = 55)</td>
<td>Follow-up at 1 month</td>
<td>Significant increase of the foot self-care knowledge score after follow-up within control group (p &lt; 0.05). Diabetes self-efficacy scores high at baseline and remained high after follow-up in all groups. There was a significant increase of diabetes self-efficacy score within control group (p &lt; 0.05) and risk assessment group (p &lt; 0.001). Baseline diabetes self-efficacy correlated with diabetes self-care behaviors.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>&quot;Recommendations for foot care education to prevent foot pathology indicate that the intervention should be simple, relevant, consistent, and repeated. Brief interventions delivered as patients interact with the health care system offer an opportunity for such interventions. The significant difference regarding foot self-care behaviors between groups at 1 month follow-up suggested that a brief education intervention may lead to increased preventive diabetic behaviors.&quot;</td>
</tr>
</tbody>
</table>
Control group: Usual care (n = 57).
Follow-up for 1 month.

self-reported foot self-care behaviors at baseline (p < 0.001) and follow-up (p < 0.05). Significant increase of self-reported foot self-care behaviors within intervention group (p < 0.01) and control group (p < 0.05). Significant difference in observed self-care behavior scores between groups (p < 0.05). Applying lotion between toes was significant difference between groups (p < 0.01). Significant difference in item of checking bottom of foot (p < 0.05).

willingness of patients and emergency department staff to participate in the intervention and follow-up suggests that interventions delivered in this environment are not a burden.

Evidence for the Use of Wound Dressings

| Armstrong 2005 RCT | 5.0 | N = 162 patients with diabetic partial foot amputation wounds up to transmetatarsal level and evidence of adequate perfusion. Also corresponding to grade 2 or 3 of the University of Texas Diabetic Foot Wound Classification system. Mean age 59 (12.8). | Negative pressure wound therapy (NPWT) group (n = 77) received Vacuum-Assisted Closure (VAC) and dressing changes every 48 hours vs. Control group (n = 85) received dressing changes only everyday unless authorized by clinician. 16 week study, follow-ups at day 7, 14, 28, 42, 56, 84, and 112. | Patients within the NPWT group (56%) showed faster healing results than control group (39%). In wound closure 0.1702 (95% asymptotic CI (0.0184-0.322) when comparing NPWT to control group. Complete wound closure higher in NPWT than control group (p = 0.005). Wounds healed by surgical closure higher in NPWT at 40% than control group at 30%. Overall, VAC system. "In conclusion, our results indicate that NPWT as delivered through the VAC Therapy System seems to be a safe and effective treatment for complex diabetic foot wounds. Treatment with NPWT resulted in a higher proportion of wounds that healed, faster healing rates, and potentially fewer re-amputations than with standard 132/162 patients male. Proportional healing at 12 and 16 weeks similar. More frequent dressing changes in usual care group (QD vs. Q48hrs), which may bias in favor of usual care. NPWT group had more complete and faster wound healing. |
helped to reduce risk of second amputation in NPWT than in control group.

Future work should look at the effect of rapid healing vs. conventional treatment at 16 weeks and fewer amputations. High dropout rate.

Viswanathan 2006 RCT
Sponsored by Bharat Biotech International Limited. No mention of COI. | N = 60 with target ulcers no less than 2 cm and no more than 50 cm² in area. Ages of 18 and 65 years. | Treatment group or rhEGF 30-g tubes twice daily until wound healed or until end of study (n = 30) vs. Placebo tubes water based and did not include active ingredient, twice daily (n = 29). Follow-up for 15 weeks. | 90% of ulcers healed in 15 weeks vs. 22 weeks in the control group. Chances of non-healing within 15 weeks 14% in test group and 50% in control. Those with an ulcer area >6 cm in test group exhibited better healing vs. control (p <0.002). | “This phase III multicenter study established the safety and efficacy of rhEGF formulated gel and found the gel healed diabetic foot ulcers faster than treatment with placebo.” | 5.0 Phase 3 trial. Study group exhibited quicker healing times compared with placebo. |

Kusumanto 2006 RCT
Sponsored by Fornix BioSciences. No mention of COI. | N = 54 with diabetic foot ulcers and/or rest pain >2 weeks, failure of conventional treatment, serious limb ischemia, type 1 or 2 diabetes; Mean age 68.4 for control group and 68.7 for phVEGF group. | Control group (n = 27) vs. Vascular endothelial growth factor (2000 μg; phVEGF<sub>165</sub>) treatment group (n = 27). Both groups received their allocated treatment at baseline and 28 days. Assessments at baseline, 7, 14, 21, 28 weeks. | At final assessment, phVEGF group had significantly higher percentage of hemodynamic improvement and improvement in skin ulcer vs. control group; hemodynamic – 33% vs. 6%, (p = 0.05). Ulcer improvement – 33% vs. 0%, (p = 0.01). | “[W]e did not meet the primary end point of a reduced amputation rate. We did, however, demonstrate that intramuscular injections of the naked plasmid DNA encoding VEGF165 (phVEGF165) significantly improved wound healing and reduced Long-term ulcer duration in controls (5 vs. 3 months). No difference in amputations. Some data favor growth factor.” | 5.0 Longer ulcer duration in controls (5 vs. 3 months). No difference in amputations. Some data favor growth factor. |
<p>| Lyons 2007 RCT | N = 46 with diabetes mellitus HbA1c 6-13%, full thickness diabetic foot ulcer below that ankle that has not reduced in size ≥30% in past 4 weeks with typical treatments, post debridement size between 0.5 to 10 cm², transcutaneous oxygen | 2.5% Talactoferrin gel group (n = 15) vs. 8.5% Talactoferrin gel group (n = 15) vs. Placebo gel group (n = 16). Groups instructed to apply gel twice daily to ulcer for 12 weeks alongside typical wound care. Assessments at baseline, 30 days, 90 days and 180 days. | 50% of participants in treatment groups reduced ulcer size ≥75% compared to 25% of participants in placebo group, approaching significance (p = 0.091). No statistically significant differences reported between varying percentages of talactoferrin gel. “[T]alactoferrin was a safe and well-tolerated treatment of diabetic neuropathic foot ulcers without associated adverse events or laboratory abnormalities. In addition, talactoferrin enhanced the rate of healing in these ulcers. A phase 3 will be required to confirm these results.” | Study Phase 2- same article as above. Small samples. High dropouts. Data suggest no differences in healing during treatments – modest differences appeared later. |</p>

<td>Kästenbauer 2003</td>
<td>RCT</td>
<td>6.5</td>
<td>N = 37 diabetic patients with moderate sized (diameter 0.5 – 3 cm) infected neuropathic (abnormal 10g-monofilament test) foot ulcer of Wagner’s grade 2 or 3. Mean age G-CSF 60.8±11.1 years, placebo 58.2±8.1 years.</td>
<td>G-CSF 5µg/kg injected subcutaneously, stopped if neutrophil count &gt;50,000/l and leukocyte count &gt;75,000/l (n = 20) vs. placebo, 0.9% sterile saline injected subcutaneously (n = 17) for a 10 day in-hospital stay. All patients put on bed rest and treated with i.v. antibiotics (clindamycin and ciprofloxacin) until inflammation improved.</td>
<td>Mean±SD leukocyte count (10^9L^-1) at day 10: G-CSF 40.8±16.3 vs. placebo 9.3±8.3 (p = 0.00005).</td>
<td>“[A]ntibiotic and non-weight-bearing therapy (bed rest) accelerated the resolution of cellulitis in infected foot ulcers. Additional treatment with G-CSF had no further beneficial effect.”</td>
<td>Small sample size. G-CSF associated with pathogen reduction faster than placebo leading to earlier resolution of cellulites.</td>
</tr>
<tr>
<td>Gough 1997</td>
<td>RCT</td>
<td>6.0</td>
<td>N=40 diabetic patients with extensive cellulitis (acute spreading skin infection with involvement of subcutaneous tissues, characterized by erythema in association with purulent discharge with or without lymphangitis). Mean age G-CSF 65 years.</td>
<td>G-CSF: initial dose of 5µg/kg daily and then lowered to 2.5µg/kg daily after 2 doses if neutrophil count higher than 25x10^9/L and stopped if neutrophil &gt;50x10^9/L (n = 20) vs. placebo, saline (n = 20) daily as an injection for 7 days. All patients received 4 antibiotics (ceftazidime, amoxicillin, flucloxacillin, and</td>
<td>Median time to hospital discharge (days): G-CSF 10 vs. placebo 17.5 (p = 0.02). Median time to resolution of cellulitis (days): G-CSF 7 vs. placebo 12 (p = 0.03). Median time to withdrawal of intravenous antibiotics (days): G-CSF 8.5 vs. placebo 14.5 (p = 0.02). Median time to negative swab culture (days): G-CSF 4 vs. placebo 8 (p = 0.02).</td>
<td>“This study showed that in diabetic patients with foot infection G-CSF treatment significantly accelerated resolution of cellulitis, shortened hospital stay, and decreased antibiotic requirements.”</td>
<td>Small sample size. G-CSF shortened hospital stay, accelerated wound healing (cellulitis), and decreased antibiotics. The mechanism may be related to increases in neutrophil superoxide production.</td>
</tr>
<tr>
<td>De Lalla 2001 RCT</td>
<td>N = 40 adult diabetic patients with limb-threatening infection (full-thickness ulcer, &gt;2cm of cellulitis with or without lymphangitis, bone or joint involvement, and systemic toxicity).</td>
<td>Conventional treatment: local treatment (debridement, daily inspection, cleaning with sterile water, disinfection with povidone iodine, surgical removal of necrotic tissues, and occlusive dressing of foot lesions, oral ciprofloxacin 750mg 2x/day plus clindamycin 300mg 4x/day) plus systemic antibiotic therapy (n = 20) vs. conventional treatment plus systemic antibiotic therapy plus glycosylated recombinant human granulocyte colony-stimulating factor (G-CSF) subcutaneously 263µg daily for 21 days (n = 20). Assessments weekly first 21 days and every NS between groups for bacterial species or number of isolates per species. Mean±SD neutrophil counts: G-CSF 25,200±3,500 vs. control 6,500±4,400 cells/mm³ (p=0.002). Amputations at 9 weeks: G-CSF 3 vs. control 9 (p=0.038)</td>
<td>“[T]he administration of G-CSF for 3 weeks as an adjunctive therapy for limb-threatening diabetic foot infection was associated with a lower rate of amputation within 9 weeks after the commencement of standard treatment.”</td>
<td>Relatively small sample size. Comparable results in, both conventional therapy and G-CSF group. At 6 months the G-CSF group had fewer amputations (3) vs. (9) in the conventional treatment group.</td>
<td></td>

| Allogeneic keratinocytes vs. vaseline gauze |
You 2012

RCT

No mention of COI.
Sponsorship, supported by grants from Tego Science (Seoul, Korea).

N = 59 type 1 or 2 diabetes, foot ulcer >1.0cm² that did not exhibit healing for 6 weeks, Wagner grade 1 or 2, and transcutaneous oxygen pressure ≥40mmHg. Mean±SD age 63.5±9.0 years (treatment) and 62.4±9.4 years (control).

Keratinocyte group (n = 27) vs. vaseline gauze (n = 32).

Follow-up weekly until wound closure or week 12.

Mean percentages of wound area reduction: 100±0 vs. 85±65% in treatment and control groups, Respectively, p <0.05.

Complete wound healing: 85% of keratinocyte-treated group vs. 59% of control group, p<0.05.

"These results indicate that cultured allogeneic keratinocytes may offer a safe and effective treatment for diabetic foot ulcers."

No ITT analysis conducted. Keratinocyte group achieved 100% ulcer healing compared to control group (59%) at 12 weeks, p <0.005.

Caravaggi 2003

RCT

Supported by a grant from Fidia Advanced Biopolymers. No mention of COI.

N = 79 patients with diabetic foot ulcer either plantar or dorsal; Mean Age not reported.

Autologous graft treatment: patients received autologous fibroblasts on Gyalograft3D which was grafted onto ulcer (n = 43) vs. Control Group treated with nonadherent paraffin gauze and scheduled at final follow-up.

65.3% in treatment group showed complete healing vs. 49.6% in control group (p = 0.191). In dorsal subgroup, treatment group showed significantly higher odds ratio (95% CI) for complete healing vs. control; 4.44 (1.09-17.7, p = 0.034).

"The results of this clinical study clearly show that the use of total offloading is so important to the tissue repair process in plantar ulcers that the efficacy of fibroblasts on Hyalograft3D and keratinocytes open label. Data suggest improved healing in dorsal ulcers compared to standard care."

</table>

Diclofenac potassium 50mg TID vs. piroxicam 20mg vs. placebo (7-day trial) for acute ankle sprain (severity not specified, no torn ligaments).

Mean statistical details provided. Volume of foot: no differences between 3 groups at 7 days. Pain at 2 days: lower VAS for diclofenac vs. placebo (p <0.0001) and piroxicam (p <0.0002). Differences continued to Day 3 vs. placebo, disappeared with piroxicam. Investigators assessment (excellent) higher for diclofenac p = 0.001.

“Diclofenac potassium was a good alternative to piroxicam for the treatment of stable (non-surgical) ligamentary injuries of the ankle, with a rapid onset of action and good overall tolerability by the patients.”

Lack of randomization, allocation, compliance details. Suggests NSAIDs provide short-term benefit for acute sprains. Possible superiority of diclofenac vs. piroxicam at this dosage although conclusions limited by lack of presented data.
preferred drug. The fact, however, that the reduction of swelling was the largest in the placebo group, might be an indication that Nature's own way in repair of tissue injury may be preferable to interference with drugs whose exact effect in the organism still remains unknown."

NYS WCB MTG – Ankle and Foot Disorders 249
<p>| Okcu 2006 RCT | 7.0 | N = 44 healthy subjects (Group A) and subjects with Grade III inversion type acute ankle sprain (Group B) | Skin temperature measurement after cryotherapy: Robert Jones bandage vs. elastic bandage vs. plaster cast vs. synthetic cast. | All groups had significant temperature reduction after use of ice packs regardless of material. Average time to reach minimum temperature was 48 minutes (RJB), 42 min (elastic), 30 minutes (Plaster) and 38 minutes (synthetic cast). Time to cooling significantly faster in casting groups compared with RJB. | “A bandage or cast does not prevent measurable skin temperature lowering by frozen ice packs both in normal and swollen ankles.” | Randomization variable was not treatment but immobilization technique. All subjects received ice packs and skin temperature was measured by thermistor. No differences found. Data suggest that cryotherapy results in skin temperature cooling regardless of material over injury. |
| Sloan Injury 1989 RCT | 5.5 | N = 122 acute ankle injuries within 6 hours of injury | Immediate ibuprofen (1200mg loading, 2400mg total per day) vs. placebo 1st 48 hours, then same ibuprofen schedule. A uniform background therapy of 20 minutes cooling, compression and elevation was given to all | Immediate vs. delayed soft tissue swelling index: % improvement 49% vs. 37% p &lt;0.01. Severity of injury: no data presented, favored immediate group p = 0.05; range of movement no differences; ability to bear weight no differences | “[I]mmediate medication with high-dose ibuprofen at 2400 mg/day should be considered in the routine treatment of moderate to severe ankle sprains, whether patients.” | Patients treated within 6-hours. Data suggest immediate NSAIDs may be beneficial for immediate pain relief and swelling relief judged at 7 days vs. placebo. |</p>

---

Zammit 2005

| RCT | 5.0 | N = 34 acute lateral ligament sprains of ankle joint | Ultrasound vs. sham ultrasound vs. control. All groups received elastic wrap (tubigrip), exercise, and ice; 6 sessions of ultrasound over 2 weeks, energy 0.25Wcm² for 10 minutes, sessions 4-6 increased to 0.5Wcm². Acute Grade I and II sprains. | Ultrasound vs. sham vs. control: Mean changes at 22 days. Pain (VAS cm): 3.9/4.0/4.2, p >0.05; Swelling reduction (cm): 1.0/1.3/1.2, p >0.05; Plantar flexion: 10°/5.2°/5/5°, p >0.05; Dorsiflexion: 4.7°/4.6°/8.8°, p >0.05. | “At the doses and duration used in this study, ultrasound is not effective in the management of acute lateral ligament sprains of the ankle joint, with respect to the following outcomes: pain, swelling, range of motion during dorsiflexion and plantar flexion, and postural stability.” | Randomization, allocation, baseline comparability details sparse. Data suggest no added benefit of ultrasound therapy to mild and moderate acute ankle sprains over placebo combined plus conservative measures of exercise, elastic wrap. Use of these modalities limits ability to differentiate effect of natural history. |
Borromeo 1997

RCT

6.0

N = 32 acute ankle sprains

Hyperbaric oxygen therapy 2 atmospheres absolute pressure vs. air 1.1 atmosphere absolute pressure treatment.

Regression analysis for oxygen vs. air, age, severity, time to initial treatment after injury: p = 0.152, p = 0.010, p = 0.0001, p = 0.995. Both groups significant reduction in pain during treatment (p <0.05): SEM for HBO = 0.19, SEM for air = 0.14.

“Analysis of objective measures of ankle function showed no difference between the subjects exposed to air and those exposed to HBO. Only two factors, subject age and initial severity of injury, affected time to recovery.”

<tr>
<td>Cleland 2013 RCT</td>
<td>7.5</td>
<td>N = 74 with inversion ankle sprain; mean age for home exercise program: 33.2, mean age for manual therapy and exercise: 37.1</td>
<td>Manual Therapy &amp; Exercise (MTEX), mobilizing and strengthening, standing and functional exercises; seen by physical therapist (PT) twice weekly for 8 sessions (n = 37) vs. Home Exercise Program (HEP), manipulations of joints, home exercises, strengthening and balancing exercises; seen by PT for 4 sessions 1 per week (n = 37). Both treatments lasted 30 minutes, advice to stay active, and education on ice, compression and elevation. Follow-up: baseline, 4 weeks and 6 months.</td>
<td>Mean percent score for FAAM activities of daily living (ADL): MTEX vs. HEP: 4 weeks: 85% vs. 70%, p &lt;0.05; 6 months: 95% vs. 85%, p &lt;0.05. Mean percent score for FAAM sports: MTEX vs. HEP: 4 weeks: 75% vs. 65%, p &lt;0.05; 6 months: 90% vs. 85%, p &lt;0.05. Mean (95 CI) for FAAM ADL: Between group differences: baseline to 4 weeks: 11.7 (7.4 to 16.1), p &lt;0.001 (in favor of MTEX); baseline to 6 months: 6.2 (0.98 to 11.5), p = 0.02 (in favor of MTEX). FAAM sports: baseline to 4 weeks: 13.3 (8.0 to 18.6), p &lt;0.001 (in favor of MTEX), baseline to 6 months: 7.2 (2.6 to 11.8), p = 0.002 (in favor of MTEX).</td>
<td>“The results suggest that an MTEX approach is superior to an HEP in the treatment of inversion ankle sprains.”</td>
<td>Good baseline comparability. Both groups had pain improvement from treatment with Manual therapy and exercise group having slightly better results for pain relief and function at 4 weeks and also 6 months vs. HEP group. However, as the intervention group had both active supervision of exercise as well as manual therapy, what was responsible for the modest differences is unclear.</td>

<td>Akermark 2013</td>
<td></td>
<td>Prospective RCT</td>
<td>N = 76 patients with a typical history and clinical diagnosis of primary Morton’s Neuroma for at least 4 months.</td>
<td>Plantar Incisions (n = 35) vs. Dorsal Incisions (n = 41). Patients' follow-up at 3 months, 12 months and 33-34 months.</td>
<td>There was a significant reduction of VAS pain score compared with baseline in both groups at all follow-up periods. (p&lt;0.001). There was no significant difference between groups at any follow-up for VAS scores. Restrictions in daily activities were reduced 77% in the plantar group and 67% in the dorsal group. These results were significant compared to baseline for both groups (p&lt;0.001), with no significant difference between groups. There were 5 complications in the plantar group 6 in the dorsal group.</td>
<td>“This study showed that pain during daily activities was equally significantly reduced in both groups at all postoperative follow-ups, with clinically good results in the plantar and dorsal groups. Results from this and other studies confirm the results from our earlier published retrospective study on Morton’s neuroma, that there is a difference in the types of complications between the 2 approaches.</td>
</tr>
<tr>
<td>Nashi 1997</td>
<td></td>
<td>RCT</td>
<td>N = 52 patients with Morton’s neuroma. Mean age among participants (44 female and 8 male) was 53 years.</td>
<td>Dorsal approach group (n = 26) vs. Plantar approach group (n = 26). Average follow-up was 3.1 years and minimum follow-up time was one year.</td>
<td>In first 2 weeks after operation, 8 patients in dorsal group able to fully bear weight compared to 0 patients in plantar group. Average return to work time after surgery was 22 days in dorsal group with 37 days in plantar group. In dorsal group 80% of</td>
<td>“The results of our study would appear to favour the dorsal approach because of the shorter in-patient period, earlier weight-bearing, a shorter time taken to return to work, a less painful scar and greater</td>

<td>Brink 1996 RCT</td>
<td>5.5</td>
<td>N = 66 stable lateral malleolar fractures, Supinatio-n-eversion Stage II</td>
<td>Aircast air-stirrup, with full weight bearing vs. DonJoy ROM Walker Brace, full weight bearing.</td>
<td>At 4 weeks 11/33 (34%) of Air and 4/33 (13%) able to do unlimited activity (p &lt;0.05). Average time for return to work 6 weeks in both groups. No differences remained at 12 weeks.</td>
<td>“[B]oth dynamic braces provided good pain relief at 4 weeks, allowed return to work at 6 weeks, and resulted in healing at 12 weeks. The Aircast was found to be easier to use and more comfortable, but the R.O.M-Walker gave greater pain relief, increased range of motion, and earlier return of ambulation.”</td>
<td>No blinding, no mention of co-interventions or lack thereof. Either brace appears sufficient; return to work equal in both groups. No clinical difference at 12 weeks between groups. Aircast cost $40 and ROM-Walker cost $110. For cost benefit Aircast seems better choice as they both returned to work on average at 6 weeks. However, pain control may dictate use of ROM-Walker in some patients.</td>
</tr>
<tr>
<td>Stuart 1989 RCT</td>
<td>4.0</td>
<td>N = 40 lateral Malleolar fractures, type II</td>
<td>Below-knee walking plaster and crutches (Group A) vs. pneumatic air stirrup and crutches (Group B) for 4-6 weeks.</td>
<td>Air cast group: Comfort at 24 hours better (p &lt;0.05); swelling at 7 days better (p &lt;0.00001). No difference in time to union. Arc of motion better (p &lt;0.0001).</td>
<td>“We advocate the use of the Aircast pneumatic air stirrup in the cost-effective management of stable ankle fractures.”</td>
<td>Lack of study details. Improvements not well correlated with long-term clinical or functional outcomes. Cost benefit showed similar overall costs; slightly more in air cast group. In Type II lateral malleolar fractures air cast appears superior.</td>
</tr>
<tr>
<td>Phillips 1985</td>
<td>5.0</td>
<td>N = 138 closed severe</td>

<td>“In patients with severe fracture of the ankle that had poor compliance with follow-up. No blinding.”</td>
<td>Non-operative vs. Operative Management</td>
</tr>
<tr>
<td>RCT</td>
<td>ankle fracture (Grade-4 supination-external rotation or pronation external rotation)</td>
<td>reduction. If satisfactory, closed treatment vs. ORIF. Unsatisfactory closed reduction: trial of reduction under general anesthesia, randomized to ORIF vs. or ASIF technique.</td>
<td>closed reduction, ORIF had better outcomes in ROM. Gait better if a medial malleolar fracture (p &lt;0.05). For closed reduction: no difference between ORIF and ASIF. Better alignment by x-ray after surgery had better clinical outcome in both groups (p &lt;0.01).</td>
<td>been satisfactorily reduced initially by closed manipulation, open reduction and internal fixation performed according to ASID guidelines gave significantly better results, as measured by our 150-point scoring system, than did closed treatment. Patients with a medial malleolar fracture and patients who were more than fifty years old both had less favorable results after closed treatment. The difference in the talocrural angle between the injured and normal sides was the only statistically significant radiographic indicator of a good prognosis.”</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Makwana 2001  
RCT | N = 47 displaced ankle fractures requiring reduction in patients age 55 and older | Acceptable post-reduction then closed treatment (CT) (below-knee plaster cast, elevation 48 hours, protected weight bearing 6 weeks, then full weight bearing) vs. ORIF: post-op below-knee cast, | Hospital stay: CT: 2.6 days, ORIF: 6.7 (p = 0.01). Immediate reduction: CT: 57%, ORIF 86% (p = 0.03). Loss of reduction: CT: 8/21 (38%), ORIF: 0/22 (p = 0.003). CRPS: CT: 0/21, ORIF 2/22 (11%). | “We recommend treating displaced ankle fractures in patients over the age of 55 years by open reduction and internal fixation.” |

| Measurement scale more weighted by subjective than objective measures. Validity of scoring system unknown. Study suggests for severe ankle fractures, ORIF may be better option, particularly with medial malleolar fractures and in persons older than 55. | No blinding, no mention of co-interventions, follow up ranged from 15-42 months. More smokers in the closed group. Study suggests in age group 55 and older ORIF has fewer treatment failures and better functional outcomes. |

</table>
N = 50 Weber type-B or C with ruptured deltoid ligament; plaster slab 2-3 days, mobilization allowed on crutches with full weight bearing at or after 6 weeks. No repair of deltoid ligament with ORIF vs. repair of deltoid ligament with ORIF. Mean average operation time 75 minutes for suture group vs. 95 for ligament repair group. Mean hospital stay 6 days; absence from work 7 weeks. No difference in symptoms and clinical findings at review. All radiographs showed normal healing. “[R]uptured deltoid ligament can be left unexplored without any effect either on early mobilisation or on the long-term result.” Assessor blinded at 17-month follow-up visit. Many details sparse. Difference in age between 2 groups. Study suggests repair of deltoid ligament in Weber type B or C fractures may not change clinical outcome.

Evidence for the Use of Operative Procedures and Fixators for Ankle Surgery
There are 4 moderate-quality RCTs incorporated into this analysis. There are 8 low-quality RCTs in Appendix 2.(688, 741, 744, 747, 749-752) (Dijkema 93; Kankare 96; Takao 04; Bucholz 94; Ahl 94; Moore 06; Kankare 95; Thordarson 01)

<tbody>
<tr>
<td>Sonden aa 1986</td>
<td>4.0</td>
<td>RCT</td>
<td>43</td>
<td>Ankle fractures requiring surgery</td>
<td>Primary mobilization group: plaster cast for 3 days. Full weight-bearing at 6 weeks vs. Immobilization group: plaster cast for 6 week with no weight bearing.</td>
<td>At 6 weeks, ROM greater in primary mobilization group (p &lt;0.01). Swelling decreased in mobilization at 12 weeks (p &lt;0.05). Pain less in mobilization group at 6, 12, 18 weeks follow-up; equal 1 year follow-up.</td>
<td>Plaster immobilization after ankle fracture results in a minor increase in morbidity. If the patient is cooperative and fixation of the fracture stable, an early mobilization (1 week) is preferable.</td>
</tr>
<tr>
<td>Tropp 1995</td>
<td>4.0</td>
<td>RCT</td>
<td>30</td>
<td>Weber B or C ankle fractures requiring ORIF</td>
<td>Double-hinged brace (received program for self training or mobility, muscular strength, and function immediately post-op) vs. plaster cast (post-op for 6 weeks, full weight bearing allowed with crutches for 2-4 weeks, then same self-training program at 6 weeks.</td>
<td>At 6 weeks 6/15 (40%) in brace group vs. 1/15 (7%) in cast group showed failure of syndesmotic staples. No correlation in displacement or fracture healing. No difference in ankle scores or ROM improvement compared to uninjured ankle at 12 months. No difference Olerud function scores. ROM: dorsiflexion better in brace group at 1 year (p &lt;.05), no correlation with functional outcomes at 12 months.</td>
<td>We conclude that the double-hinged brace is appreciated by the bearer. Higher ROM was noted in the brace group, but the obvious advantage of the brace is subjective to the bearer. There is a higher expense for the brace than for the plaster cast. Long-term results of brace and case treatment are comparable.</td>
</tr>
</tbody>
</table>

Randomize d into groups (both groups non-weight bearing at least 6 weeks) Immobilization postoperatively in below the knee cast. PT after 6 weeks. Weeks 56.5 vs. 52.4 (p = 0.03). Return to work: Early mobilization mean days 53.8, immobilization 106.5 (p = 0.007). Group for RTW analyses. Suggests faster return to work with functional bracing and early mobilization with no increase in adverse events.

"Without stratification of groups, the functional results after nonoperative care of displaced intra-articular calcaneal fractures were equivalent to those after operative care. However, careful stratification of the patient provided a..."
and managed operatively had significantly higher satisfaction scores (p = 0.001).

Population and clinical outcome information distinguishes certain features that support surgical care for displaced intra-articular calcaneal fractures. Statistical analysis demonstrated that women, patients who were not receiving workers’ compensation, younger males, patients with a higher Böhler angle, patients with a lighter workload, and those with a single, simple displaced intra-articular calcaneal fracture have better results after operative treatment than after nonoperative treatment."

Data suggest no difference in general population between treatments, but ORIF may be superior to non-operative management in specific populations.

<p>| Howard 2003 RCT | 5.5 | N = 424 displaced intra-articular calcaneal fractures with disruption of posterior facet &gt;2mm | Non-operative treatment (NOP). Pain management, RICE, non-weight bearing. PT and full weight bearing at 6 weeks vs. ORIF, lateral approach. Full weight ORIF had more clinical complications than NOP. NOP 42.218 (19%) had complications that led to surgery; 2/218 (0.01%) had late compartment syndrome. 37/218 (16%) had secondary late fusion. &quot;Outcome scores in this study tend to support ORIF for calcaneal fractures. ORIF patients are more likely to develop complications, however. Certain patient populations have a high incidence of...&quot; | Second report of Buckley 2002. <tr>
<td>O'Brien 2004</td>
<td>5.5</td>
<td>319</td>
<td>Non-operative management vs. ORIF measuring gait satisfaction scores at 2-8 years.</td>
<td>No difference in SF-36 scores between groups at 2 to 8 years follow-up (p = 0.22). Age &lt;30 with ORIF = improvement in gait scores compared to non-op (p = 0.02). Quality of fracture reduction no different between groups. Bohler angle in non-op group of &gt;15° compared to &lt;0° had better gait scores (p = 0.00).</td>
<td>“[P]ersonal gait satisfaction scores were not significantly affected by treatment method in patients with DIACF at 2-8 years follow up. However, gait scores were better in patients treated with ORIF if they were younger than 30 years of age, had no worker’s comp claims, had jobs requiring a moderate workload before injury and had restoration of Bohler angle to above 0 degrees.”</td>
</tr>
<tr>
<td>Thordarson 1996</td>
<td>4.0</td>
<td>30</td>
<td>Non-operative management with early mobilization and delayed weight bearing at 8 weeks vs. ORIF with early mobilization and delayed weight bearing.</td>
<td>Pain on extremes of motion in 25% of ORIF and 100% in non-operative group. Average functional score of 86.7 in ORIF group vs. 55.0 in non-operative group. (p &lt;0.0001).</td>
<td>“Our study demonstrated markedly superior results with operative treatment of fractures versus non-operative treatment.”</td>
</tr>
</tbody>
</table>

“1/218 developed CRPS. ORIF: 11/206 (0.5%) deep wound infections. 2/206 developed PE. 4/206 had compartment syndrome. complications regardless of the management strategy chosen (WCB patients, Sanders type IV patients).”

Disruption of posterior facet >2mm has fewer complications than ORIF.

Third report of same population (see Buckley 2002). Post-hoc analyses suggests restoration of Bohler angle is predictive of function. Data also suggests those with workers’ comp claims have worse outcomes regardless of treatment type for this injury.

## Appendix D.4 - Low-Quality Randomized Controlled Trials and Non-randomized Studies

The following low-quality randomized controlled studies (RCTs) and other non-randomized studies were reviewed by the Evidence-based Practice Ankle and Foot Panel to be all inclusive, but were not relied upon for purpose of developing this document’s guidance on treatments because they were not of high quality due to one or more errors (e.g., lack of defined methodology, incomplete database searches, selective use of the studies and inadequate or incorrect interpretation of the studies’ results, etc.), which may render the conclusions invalid. ACOEM’s Methodology requires that only moderate- to high-quality literature be used in making recommendations. (835) (Harris JOEM 08)

**Nistor 1981**

N = 105 closed acute ruptures of Achilles tendon

Surgery (end to end suture) vs. progressive casting.

“Absence from work varied depending on work. It averaged thirteen weeks (0-30) in surgically treated groups and nine weeks (0-44) in non-surgically treated groups (P <0.05).” No differences in plantar flexion strength or increases in tendon size.

“Results of both surgical and non-surgical treatment of acute ruptures of the tendo Achillies were good, and they confirmed the results reported previously. There were only minor differences in the groups, but the period of morbidity was shorter, the complaints were fewer, and no hospital stay was needed in the conservatively treated patients. ...The treatment of choice should be non-surgical.”

Quasi randomized (odd-even day). No blinding of assessment. Casting group was quicker to return to work, although also had higher re-rupture rate (8% vs. 4%).

### Melnyk 2009
RCT

| N = 26 healthy subjects | Whole body vibration training x 4 weeks vs. no training. | No differences in latencies and reflex activity in both long peroneal and tibialis muscles in response to ankle sprain simulation or ankle inversion motion. | “…it is unlikely that 4-weeks of whole body vibration training has beneficial effects on ankle joint stability in the case of an ankle inversion motion.” | Lack of study details. Results are of unknown clinical significance as the subject population had no orthopedic injuries and outcomes measures did not include incidence of injury post training. |

### Foot Orthotics for Prevention

### Fauno 1993

| See Evidence Table for Plantar Fascitis (Orthoses) above. |  |

### Stretching/Strengthening Exercises

#### Pope 2000
Cluster-RCT

| N = 1,589 male army recruits (39 platoons) | Stretching vs. no stretching for prevention of ankle sprain. | 1538 recruits, 170 (11%) transferred to officer training before end of training. Incidence of lower-limb injury: 3.5 per 1,000 training days. Hazard ratio .95 (95% CI .77-1.18). Ligament sprain, ankle joint: control vs. stretch; 27 vs. 19 out of 175 and 158. | “[P]reexercise muscle stretching does not produce a clinically worthwhile reduction in the risk of lower-limb injury. Injury risk is strongly associated with age and 20mSRT scores. This suggests that fitness may be a modifiable risk factor for injury.” | Cluster randomization as subjected assigned to platoon by surname. Platoons then randomized although method unclear. Lack of study details. Ankle specific analysis not presented. |

#### Puls 2007
RCT

| N = 30 healthy subjects | No training vs. Thera-band training 3 times a week vs. Thera-band 5 times a week for 6 weeks. | Primary outcome of postural control measured on force plate. There were no differences related to intervention. | “[F]ound no significant improvements in static postural control among healthy individuals related to a specific Thera-band training regiment after six weeks of training regardless if the exercises were performed three or Sparse study details. No compliance to training data presented. Study suggests Thera-band training provides no benefit to healthy population. Results are of uncertain clinical significance. |  |
Ekstrand 1983 RCT 1.5 N = 180 male soccer players Warm-up exercise program (passing soccer ball, flexibility stretches, cool down) vs. control. Prophylactic program vs. nonobservance prophylactic program vs. control number of injuries: Strains 5/1/23, lower leg injuries (traumatic) 0/0/3, lower leg injuries (overuse) 1/0/7, ankle sprain in players with history of previous strain 0/2/9 (p <0.05), reinjuries 0/0/13, knee sprains with ALRI 0/0/3, injuries due to fouls 1/0/6, injuries at training camp 1/0/8, injuries connected with prophylactic program 8/3/72, other injuries 12/0/21, total 20/3/93. “[T]he proposed prophylactic program, including close supervision and correction by doctors and physiotherapists, significantly reduces soccer injuries.” Sparse study details. Intervention appears to have reduced injury and ankle sprains.

Niedermann 1981

2.5

RCT

N = 444 acute ankle sprains

Surgery plus cast for 5 weeks vs. cast for 5 weeks; randomized portion likely moderate and severe sprains.

Outcomes measures: strapping (non-randomized Grade I) vs. plaster vs. operation. No differences in return to sport, functional recovery, pain when walking. Good Results: 76% plaster vs. 81% operative (p = NS).

“[T]here was no statistically significant difference between the results of conservative and operative treatment of rupture of the lateral ligaments of the ankle.”

Sparse study details. Only 209/444 randomized. Results did not clearly indicate if randomized portion considered separately. High drop-out rate at 1-year follow-up (37%). No differences in treatment in any major indicator.

van den Hoogenband 1984

2.5

See Casting above.

Gronmark 1980

2.0

See Casting above.

Clark 1965

1.5

RCT

N = 24 with injuries of the lateral ligaments of ankle

Surgical repair vs. cast immobilization.

Surgical vs. cast: Average return to full duty (weeks): 12 vs. 8, p not specified. Excellent results (time measured not indicated) 9/12 vs. 9/12

“In terms of function…there was no difference between the two groups. Surgical treatment, however, is associated with a greater morbidity.”

Timing of outcome measures unclear. Duration of conservative group immobilization not defined. Operative group received PT. Suggests outcomes similar in functional measures. Earlier return to work in cast group.

  - **N = 42**
  - With displaced ankle fractures requiring reduction (Presumably AO B and C level of fracture)
  - Closed reduction and long leg plaster cast 6 weeks with early weight bearing encouraged vs. ORIF using AO technique. Below-knee plaster cast 6 weeks with early weight bearing.
  - At 20 weeks from injury more of the closed reduction group regained normal movements and foot position.
  - "If a good reduction can be achieved and maintained then closed treatment is as good as operative treatment in the short term and, indeed, seemed to result in a quicker return to normal gait."

- **Salai 2000**
  - **RCT**
  - **N = 84**
  - Elderly patients with displaced tri-malleolar ankle fractures with manipulation under anesthesia for reduction
  - Conservative therapy including short leg cast and mobilization vs. open reduction surgery.
  - Total ankle scores: 91.37±8.96 for non-operative group vs. 75.22±14.38 for operative group, p = 0.001.
  - "Consideration of a non-operative approach to the treatment of well-reduced ankle fractures in the elderly."

- **Dijkema 1993**
  - **RCT**
  - **N = 43**
  - Closed non-comminuted
  - ORIF with biofix implants vs. ORIF
  - Patients with biodegradable rods scored an average of 94.5 point on Olerud's "Patients treated with the biodegradable material reported slightly less pain. Lack of study details. No blinding, no details on control of co-

<td>RCT</td>
<td>N = 37 displaced malleolar fractures aged 65 and older</td>
<td>Self-reinforced polyglycolide rods and screws (n = 16) vs. metallic screws and plates (n = 19)</td>
<td>Re-displacement occurred in 1/16 (6%) in biodegradable group. Exact reduction obtained in 15/16 (94%) biodegradable group and 16/19 (84%) metallic group. “It seems that displaced malleolar fractures can be treated successfully also in elderly people using totally biodegradable self-reinforced polyglycolide rods and screws when comminution does not require plate fixation.” Lack of study details. Suggests biodegradable implants achieved similar outcomes to metallic screws and plates in elderly patients with displaced malleolar fractures.</td>

**Post-Operative Care – Electrical Stimulation**

- **Hernandez** 2006 RCT
- **N = 24** closed ankle fractures requiring surgery
- **Intervention**: Cast plus percutaneous electrical stimulation (Myospare) for 6 weeks vs. cast for 6 weeks.
- **Outcome**: No adverse effects from Myospare reported. Reported trend (p >0.05) toward improvement in calf diameter as well as in dorsiflexion and plantarflexion in Myospare group.
- **Conclusion**: The use of the Myospare device under a cast in patients after surgical fixation of ankle fractures has been demonstrated as feasible and safe. In this pilot study a trend toward enhanced recovery was apparent in the treatment group.

**Calcaneal Fractures – Non-operative vs. Operative Care**

- **Parmar** 1993 Quasi-RCT
- **N = 80** non-displaced calcaneal fractures (include but not randomized) and displaced intra-articular calcaneal fractures
- **Intervention**: Non-operative (elevation for 5-7 day with mobilization, than non-weight bearing cast for 6-8 weeks vs. ORIF with post-op cast and non-weight
- **Outcome**: Displaced fractures: increased pain scores on VAS correlated with significant delays in return to employment (p <0.002), return to full recreational activities (p <0.01), and reduced patient satisfaction (p <0.000002)
- **Conclusion**: Operative treatment of this joint is not likely to improve outcome.
